Decreasing Photoperiod inhibiting Metamorphosis in an Insect

Anthrenus verbasci (L.) (Col. Dermestidae) has a two-year life-cycle (semivoltine) under outdoor temperature conditions in southern England, spending the first winter as a young larva and the second as a fully grown larva¹. Under constant conditions in the laboratory larvæ may be either uni- or semivoltine according to temperature. The percentage of larvæ with a univoltine life-cycle increases from 0 at 15° C. to 100 at 25° C. The larvæ have been shown to possess an endogenous and persistent rhythm controlling the onset of diapause². Each cycle of the rhythm consists of a period of active growth (with moulting and/or pupation) followed by diapause. Under constant conditions the length of the cycle is about 44 weeks, but this is extended to an annual cycle, under outdoor conditions, by the insertion of a period of dormancy after the completion of diapause.

The nature of this dormant period, and the agencies controlling it, were examined by rearing isolated larvæ: (1) under outdoor temperature conditions in a Stevenson screen and (2) under constant temperature conditions (20° C.). In both (1) and (2) 80 larvæ were kept in natural daylight and 80 in continuous darkness. There were two levels of relative humidity, 30 per cent

and 70 per cent (with imperfect control when the temperature fluctuated). There were also two regimes of observation; half the larvæ were examined fortnightly and the ecdysed skins noted, while the other half were only examined immediately prior to the expected time of pupation. After this time, that is, from about the 20th week, both groups were examined weekly until the end of the experiment. The above differences in humidity and in frequency of observation did not affect the main result. Altogether 320 isolated larvæ were observed, but only those which successfully completed development are recorded in Fig. 1.

These experiments demonstrated the following points. First, under outdoor conditions, temperature was the important factor controlling the time of pupation—light appeared to play no part (Fig. 1 A and B). Secondly, under conditions of constant temperature and natural daylight the earliest pupations were delayed by periods up to about 13 weeks. This is shown by reference to the control experiments (Fig. 1 D) in which pupation commenced at the 64th week, whereas larvæ exposed to light (Fig. 1 C) were inhibited until the 76th week—the difference between C and D (12 weeks) is indicated by line a. (The narrowness of the range of pupation times in A and B compared with D reflects the fact that diapause was completed by all individuals in A and B before the temperature rose sufficiently to stimulate pupation. C can be regarded as intermediate in this respect.)

It would seem, therefore, that towards the end of a two-year cycle, larvæ which would in the absence of light pupate in October are inhibited from pupating until the following January, if they are exposed to natural daylight. Day-length is decreasing during this period, and this is thought to be the stimulus responsible for the inhibition of pupation.

Fig. 1. Frequency of pupation times when larval development has taken place under various combinations of light and temperature. C and D, constant temperature (20° C.). (An accident occurred, and for this reason D represents a combination of two controls, running simultaneously.) One black square marks the time of pupation, to the nearest week, of one individual. Observations were made weekly.

This type of response is of considerable ecological significance particularly in a semivoltine species. Since the amount of growth that takes place during an active period of the cycle is directly dependent on the temperature, larvae developing over a period of two years, in habitats of widely different mean temperature, might reach the fully grown stage at almost any time of the year. A seasonal signal is therefore required to restrict emergence to the spring. Synchronized emergence is important for *A. verbasci*: since the adult life is relatively short, it greatly increases the chances of mating. This must be of considerable importance in areas where the population is small or thinly dispersed.

Anthrenus verbasci (L.) is the first insect in which it has been shown that metamorphosis is prevented during a period of decreasing day-length. Corbet³ showed that diapause in the emperor dragonfly (*Anax imperator* Leach) was prevented by an increasing photoperiod. These two examples seem to be the only ones in which insects have been shown to be sensitive to a changing photoperiod rather than to one of fixed length.

GENETICS

Evidence for a Gm^{ab} Allele in the Gm System of American Negroes

RHESUS-POSITIVE [Rh(+)] red blood cells coated with selected incomplete anti-D sera may be caused to agglutinate by serum from selected patients with rheumatoid arthritis¹. The agglutinating activity of the rheumatoid arthritis serum may be inhibited by sera from some normal individuals¹. Inhibiting normal sera are called $Gm(+)$, non-inhibiting normal sera are called $Gm(-)$. Four Gm factors detected by different pairs of rheumatoid arthritis and anti-D sera have been reported. They are Gm^a ¹, Gm^b ², Gm^x ³ and Gm -like⁴.

In Europeans Gm^a and Gm^b are due to co-dominant alleles, Gm and Gm^b . A third dominant allele at this locus, Gm^{ax} ², determines the factors Gm^a and Gm^x . Table 1 lists the presumed genotypes for the phenotypes thus far observed among white populations. Family studies^{2,3} support the postulated genotypes. The fourth factor, Gm -like, is absent or rare in Whites⁴. It occurs in American Negroes⁴ and in Negroid populations from Java and Africa; but it has not been observed in pure Mongoloid populations⁵. Its genetic relation to Gm^a , Gm^b and Gm^{ax} is unknown⁴.

Table 1. PHENOTYPES AND POSSIBLE GENOTYPES FOR Gm^a , Gm^b AND Gm^x IN CAUCASOIDS

Phenotypes	Presumed genotypes
$Gm(a+b+x+)$	Gm^{ax}/Gm^b
$Gm(a+b-x+)$	Gm^{ax}/Gm^{ax} ; Gm^a/Gm^{ax}
$Gm(a+b+x-)$	Gm^a/Gm^b
$Gm(a+b-x-)$	Gm^a/Gm^a
$Gm(a-b+x-)$	Gm^b/Gm^b

While only 56.96 per cent of 2,635 Europeans were found to be $Gm(a+)$ (summarized from various reports in ref. 4), 95 per cent of 74 Eskimos¹, 100 per cent of 110 Negroids (Javanese, Djuka Negroes, Micronesians and West Africans)⁵, 100 per cent of 105 Mongoloids (Eskimos, Athabascans, Oyana and Carib Indians)⁵, and 100 per cent of 449 natives of Dakar⁶ were found to be $Gm(a+)$. Since Gm^b is an allele of Gm^a one would expect Gm^b to be absent among Negroids and Mongoloids with no white ancestry and rare among those with white ancestry. This communication is a report of our tests of this expectancy.

Sera from Baltimore populations of Negroes and Whites were tested at Johns Hopkins Hospital; sera from Cleveland populations of Negroes and Whites were tested at Western Reserve University. All tests were done on slides by the method reported by Harboe and Lundevall², with concentrations adjusted to suit the reagents used. The reagents are listed in Table 2. All tests were done with homozygous Rh(+) cells.

Table 2. REAGENTS USED TO TEST FOR Gm^a AND Gm^b

Laboratory	To test for	RA	Anti-D
Johns Hopkins	Gm^a	B785	D4
	Gm^b	B30	D8
Western Reserve	Gm^a	Kimb.	Bowers
	Gm^b	Ham.	Bomb.

The results of the tests on the Negro and White populations are shown in Table 3. The phenotypic distributions in the samples from the two institutions agree within statistical limits ($P > 0.5$, for the serum samples from Negroes, and $P > 0.05$ for the serum samples from Whites).

Table 3. TESTS OF SERUM FROM AMERICAN NEGROES AND AMERICAN WHITES FOR Gm^a AND Gm^b

Laboratory	No. tested	A Negroes			
		$Gm(a+b+)$		$Gm(a+b-)$	
		No.	%	No.	%
Johns Hopkins	252	240	95.2	7	2.8
Western Reserve	371	353	95.1	7	1.9
Total	623	593	95.2	14	2.2
Laboratory	No. tested	B Whites			
		$Gm(a+b+)$		$Gm(a+b-)$	
		No.	%	No.	%
Johns Hopkins	143	61	42.6	14	9.8
Western Reserve	106	60	56.6	9	8.5
Total	249	121	48.6	23	9.2

The unexpected result is that the combined data of the two institutions show that 95 per cent of American Negroes are $Gm(a+b+)$. That this observation is not due to technical errors is shown by the data for American Whites, which agree with those previously reported for European Whites⁴. Unpublished data of Steinberg, Stauffer, Fudenberg and Blumberg indicate that Mongoloid populations are also essentially 100 per cent $Gm(a+b+)$.

There is no reason to suppose that the Gm^a and Gm^b factors are not genetically determined in coloured peoples, but a direct test of this is not possible with the available samples. Assuming genetic determination, the genotypic alternatives are that nearly all coloured individuals are heterozygous for Gm^a and Gm^b with heterozygosity maintained by a system of balanced lethals, or that coloured populations are homozygous for an allele, Gm^{ab} , which determines both Gm^a and Gm^b . The former alternative requires that 50 per cent of all conceptions end in death to maintain heterozygosity and is therefore untenable. We accept the latter alternative.

The phenotypes and their possible genotypes (assuming a Gm^{ab} allele) for the Gm^a and Gm^b factors in Negroes are shown in Table 4. From this table it may be seen that the $Gm(a + b -)$ and the $Gm(a - b +)$ individuals are homozygotes, hence the square roots of their frequencies provide estimates of the frequency of the alleles Gm^a and Gm^b , respectively, in American Negroes. These values (from the combined samples) are 0.150 ± 0.020 for Gm^a , and 0.160 ± 0.020 for Gm^b .

Table 4. PHENOTYPES AND POSSIBLE GENOTYPES FOR Gm^a AND Gm^b IN NEGROES

Phenotypes	Possible genotypes
$Gm(a + b +)$	Gm^{ab}/Gm^{ab} ; Gm^{ab}/Gm^a ; Gm^{ab}/Gm^b ; Gm^a/Gm^b
$Gm(a + b -)$	Gm^a/Gm^a
$Gm(a - b +)$	Gm^b/Gm^b

If we make the reasonable assumptions that the Negro ancestors of the American Negro were homozygous for Gm^{ab} , and that the alleles Gm^a and Gm^b in American Negroes were derived from White ancestors, the sum of their frequencies (0.310) is a measure of the proportion of the genotype of American Negroes which has been derived from these White ancestors. This value agrees with the value derived by Glass and Li⁷ (0.306) on the basis of the R^0 allele of the Rh groups and thus reinforces their conclusion that White ancestors have contributed some 30 per cent of the genotype of American Negroes.

Chromosome Number in the Blue Fox (*Alopex lagopus* (L.))

THE materials examined consisted of testes from five farm-bred blue foxes (*Alopex lagopus* (L.)) which were killed by electrocution during the breeding season. The testes were immediately removed, teased in distilled water where they remained for about 10 min. and then the pieces were put in either aceto-orcin or 50 per cent acetic acid. From the aceto-orcin coloured preparations, temporary slides were made by the usual squash methods. The preparations fixed in 50 per cent acetic acid were squashed in the same manner and coloured by the Feulgen method¹.

The testicular material under observation contained numerous spermatogonial cells undergoing division. Careful counts of only those metaphase plates which seemed to be intact gave 50 chromosomes as the diploid number (Fig. 1a). The diploid complex was remarkable for its comparatively small chromosomes.

Fig. 1. Chromosomes of the blue fox (*Alopex lagopus*). a, Mitotic metaphase with 50 chromosomes. The X and Y chromosomes are indicated; b, first meiotic metaphase with 25 bivalents. The X—Y complex is indicated; c, the second meiotic division. ($\times c, 950$)

Because of this the identification of the different chromosomes presented some difficulties. It was found, however, that the diploid complex consisted of 38 meta-centric or sub-metacentric, 11 teleo-centric and one dot-like chromosome where the centromere could not be identified. This dot-like chromosome was remarkably smaller than the other ones and apparently has no counterpart. It seems justifiable to consider this to be one of the sex-chromosomes. The other element of the sex-chromosomes seemed to be a rod-shaped chromosome of medium size.

Counts from both the first and the second meiotic division confirmed the number given. The metaphase of the first meiotic division showed 25 bivalents (Fig. 1b). Here it was difficult to distinguish the X—Y complex. It seems that more than one pair of chromosomes have precocious condensation. The second meiotic division was in most cases difficult to count as the chromosomes were small and often lumped together and were diffuse in appearance; but also here 25 chromosomes were found (Fig. 1c).

The results obtained in this investigation show that the diploid number of chromosomes in the male blue fox (*Alopex lagopus*) is 50. This is not in agreement with results described earlier. Andes² has reported that the number of chromosomes in the blue fox (*Vulpes lagopus*) is approximately between 50 and 60 diploid. He found also 26 tetrads in the first meiotic division. He was, however, unable to distinguish the sex-chromosomes. Wipf and Shackelford³ agreed with the counts of Andes. They found 52 chromosomes diploid. Neither could these authors find sex-chromosomes on the basis of heteropycnosis, differences in size or other morphological characters.

FORTHCOMING EVENTS

(Meetings marked with an asterisk * are open to the public)

Monday, October 10

INSTITUTION OF CHEMICAL ENGINEERS (at the Royal Institution, Albemarle Street, London, W.1), at 8 p.m.—Symposium on "Surface Effects and Liquid Behaviour".

UNIVERSITY OF LONDON (at the Institute of Education, Malet Street, London, W.C.1), at 5.15 p.m.—Dr. J. M. Tanner (Institute of Child Health): "Physical Development".*

Tuesday, October 11

UNIVERSITY COLLEGE (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. C. W. Allen: "Eclipses of the Sun".*

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (joint meeting with the AGRICULTURE GROUP, at 14 Belgrave Square, London, S.W.1), at 2.45 p.m.—Mr. O. S. Rose, Dr. S. N. Adams, Dr. R. Hull and Dr. R. A. Dunning: "Sugar Beet—Cultivation and Pest Control Measures".

ZOOLOGICAL SOCIETY OF LONDON (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

CEMENT AND CONCRETE ASSOCIATION (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Mr. L. A. Ashton and Mr. S. C. O. Bate: "Fire Resistance of Pre-stressed Concrete Beams".

INSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENT AND CONTROL SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. C. G. Garton: "Time and Insulation" (Chairman's Address).

ROYAL SOCIETY OF MEDICINE, EXPERIMENTAL MEDICINE AND THERAPEUTICS SECTION (at 1 Wimpole Street, London, W.1), at 5.30 p.m.—Discussion on "The Kinetics and Control of Erythropoiesis".

UNIVERSITY OF LONDON (in the Main Lecture Theatre, New Physics Building, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 5.30 p.m.—Prof. R. Nevalinna (Helsinki): "Absolute Analysis".*

ILLUMINATING ENGINEERING SOCIETY (at the Royal Institution, Albemarle Street, London, W.1), at 6 p.m.—Dr. W. S. Stiles, F.R.S.: "Lighting and Research" (Presidential Address).

Wednesday, October 12

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Prof. G. H. Laith: "Biochemical Basis of Liver Function Tests".*

BRITISH COAL UTILIZATION RESEARCH ASSOCIATION (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Dr. F. J. Dent: "The Hydrogenation of Coal to Methane" (Ninth Coal Science Lecture).

CHALLENGER SOCIETY (at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 5.45 p.m.—Dr. Jacques Piccard: "With the Trieste in the Challenger Deep".

INSTITUTION OF ELECTRICAL ENGINEERS, EDUCATION DISCUSSION CIRCLE (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Laboratory Work for the Part III Examination", opened by Dr. P. F. Soper.

BRITISH INSTITUTION OF RADIO ENGINEERS, ELECTRO-ACOUSTICS GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Prof. Colin Cherry: "Electro-Acoustics for Human Listeners" (Inaugural Meeting).

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at the Royal Institution, 21 Albemarle Street, London, W.1), at 7 p.m.—Prof. V. N. Kondratiev (U.S.S.R. Academy of Sciences): "Energy Exchange in the Interaction of Particles under Electric Discharges" (Second Humphry Davy Lecture).

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (joint meeting with the BIOLOGICAL METHODS GROUP of the SOCIETY FOR ANALYTICAL CHEMISTRY, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Dr. J. H. Hamence, Mr. P. H. Needham, Mr. J. G. Reynolds and Mr. R. Goulden: "Biological Assay of Insecticidal Residues".

WOMEN'S ENGINEERING SOCIETY (at "Hope House", 45 Great Peter Street, London, S.W.1), at 7 p.m.—Mr. J. Race: "The Use of Microwaves in Telecommunications".

Thursday, October 13

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. H. B. Ryoroff: "Proteas of the South Western Cape"; Dr. L. E. Richdale: "The New Zealand Mutton Bird".

UNIVERSITY OF LONDON (at the Royal Veterinary College, Royal College Street, London, N.W.1), at 5 p.m.—Prof. C. W. Hemmens (Sydney): "The Biological Assay of Oestrogenic and Anti-Oestrogenic Activity". (Further lecture on October 20.)

INSTITUTION OF ELECTRICAL ENGINEERS, UTILIZATION SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. M. Ferguson: "Developments in Electrical Plant for Industry" (Chairman's Address).

SOCIÉTÉ DES INGÉNIEURS CIVILS DE FRANCE (joint meeting with the INSTITUTION OF STRUCTURAL ENGINEERS, at 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—M. Jean Baillet and M. Max Tourasse: "Pre-stressed Concrete Pressure Vessels for Nuclear Reactors at Marcoule".

CHEMICAL SOCIETY (in the Large Chemistry Lecture Theatre, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 7.30 p.m.—Prof. R. A. Raphael: "Recent Studies on Many-Membered Rings" (Tilden Lecture).

RADAR AND ELECTRONICS ASSOCIATION (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7.30 p.m.—Mr. P. S. Carrut: "Colour Television".*

Friday, October 14

ASSOCIATION OF APPLIED BIOLOGISTS (in the Lecture Hall of the British Museum (Natural History), Cromwell Road, South Kensington, London, S.W.7), at 10.45 a.m.—Symposium on "Soil Fauna in Relation to Soil Formation and Fertility".

ANTIQUARIAN HOROLOGICAL SOCIETY (at 35 Northampton Square, London, E.C.1), at 6.30 p.m.—Opening and House-Warming, followed by Mr. Cecil Clutton: "Two Constant-Force Chronometers".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN ORGANIC CHEMISTRY, and an ASSISTANT, Grade A, FOR GENERAL CHEMISTRY at Birkenhead Technical College—The Director of Education, Birkenhead Education Committee, 63 Hamilton Square, Birkenhead (October 12).

METEOROLOGICAL OFFICERS (with a first- or second-class honours degree (or equivalent) in physics or mathematical physics or mathematics or engineering or degree (or equivalent) in meteorology) in the Irish Meteorological Service—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (October 14).

ASSISTANT EXPERIMENTAL OFFICER (with at least two subjects at advanced level to include chemistry, zoology or biology, and preferably a knowledge of French and/or German), for work which includes scanning and abstracting scientific literature—The Director, Pest Infestation Laboratory, Agricultural Research Council, London Road, Slough, Bucks (October 15).

ASSISTANT EXPERIMENTAL OFFICERS (2) (with at least two scientific subjects at advanced level, or equivalent) AT THE AGRICULTURAL RESEARCH COUNCIL'S PEST INFESTATION LABORATORY, one for work on insects attacking stored foodstuffs, and the other for work on mycological problems connected with food storage—The Director, Pest Infestation Laboratory, Agricultural Research Council, London Road, Slough, Bucks (October 15).

HEAD OF THE DEPARTMENT OF SCIENCE, Grade III—The Academic Registrar, Hatfield Technical College, Hatfield, Herts (October 15).

HOSPITAL BIOLOGIST (with a first- or second-class honours (B.Sc.) degree in biochemistry or physiology or similar qualifications), for routine and research investigations involving bioassays and chemical procedures—The Deputy Director, Vincent Square Laboratories of Westminster Hospital, 124 Vauxhall Bridge Road, London, S.W.1 (October 15).

LECTURER (with an honours degree in science, preferably in chemistry) FOR WORK ON METHOD IN SCIENCE, to help undergraduate students of science and engineering to clarify their attitudes to science through using discussion and other methods of teaching which have already been developed in the college—The Registrar, Brunel College of Technology, Woodlands Avenue, Acton, London, W.8 (October 15).

LECTURERS (2) (with an honours degree in chemistry, with teaching and research or industrial experience) IN THE DEPARTMENT OF CHEMISTRY, one for Organic and one for Inorganic Chemistry—The Principal, Whitehaven College of Further Education, Whitehaven, Cumberland (October 15).

PRINCIPAL OF THE INSTITUTE OF AGRICULTURE, Moulton—Chief Education Officer, County Education Offices, Northampton (October 15).

READER IN MATHEMATICS—Prof. Titchmarsh, Mathematical Institute, The University, Oxford (October 15).

SENIOR LECTURER (with high academic qualifications and preferably industrial and research experience) IN PHYSICAL CHEMISTRY—The Registrar, Lanchester College of Technology, Priory Street, Coventry (October 15).

LECTURER IN PHYSICS AND/OR CHEMISTRY—The Principal, Bede College, Durham (October 22).

LECTURER IN STATISTICS—The Registrar, University College of North Staffordshire, Keele, Staffs (October 24).

ASSISTANT LECTURER (with special qualifications in genetics, cytology or taxonomy) IN BOTANY—The Secretary, The Queen's University, Belfast (October 31).

LECTURER/ASSISTANT LECTURER (preferably with a good honours degree in either agricultural science or veterinary science, suitable research and teaching experience, and previous practical experience in animal husbandry, including the breeding, feeding and management of farm livestock, preferably under tropical conditions) IN ANIMAL SCIENCE at the University of Malaya, Kuala Lumpur—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Malaya and London, October 31).

PRINCIPAL OF ABERDEEN COLLEGE OF EDUCATION—The Principal, The College of Education, St. Andrew Street, Aberdeen (October 31).

CHAIR OF ANATOMY—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (November 5).

LECTURER IN ORGANIC CHEMISTRY at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, November 7).

RESEARCH FELLOWS (with interests in the following fields: (a) geomorphology, (b) biogeography (including plant ecology), or (c) social or economic geography) IN THE DEPARTMENT OF GEOGRAPHY, Research School of Pacific Studies, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, November 7).

CHAIR IN PLANT SCIENCE—The Registrar, Massey Agricultural College (University of New Zealand), Palmerston North, New Zealand (November 30).

DEMONSTRATORS (preferably with an honours degree) IN INORGANIC AND PHYSICAL CHEMISTRY at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, November 30).

LECTURER IN METALLURGY at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, November 30).

LOGAN CAMPBELL CHAIR IN FOOD TECHNOLOGY—The Registrar, Massey Agricultural College, University of New Zealand, Palmerston North, New Zealand (November 30).

SENIOR LECTURER or LECTURER IN MINING at the University of Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, November 30).

SCIENTIFIC OFFICER (honours graduate in zoology), for work on plant parasitic nematodes—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (November 30).

WALTER CLARK BUCHANAN CHAIR IN AGRICULTURAL ECONOMICS AND FARM MANAGEMENT—The Registrar, Massey Agricultural College (University of New Zealand), Palmerston North, New Zealand (November 30).

LECTURERS or ASSISTANT LECTURERS (2) (with at least a good honours degree in zoology or equivalent qualification, experience in teaching and research, and preferably with a special knowledge of entomology or arthropod zoology in general for one of the two posts) IN THE DEPARTMENT OF ZOOLOGY at the University of Malaya, Kuala Lumpur—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Kuala Lumpur and London, December 1).

ASSISTANT, Grade B (graduate, preferably with teaching and/or research and/or industrial experience, capable of taking classes to B.Sc. (General) degree and H.N.C. level, and preferably a member of the Royal Institute of Chemistry), IN CHEMISTRY—The Clerk to the Governors, Mid-Essex Technical College and School of Art, Market Road, Chelmsford, Essex.

ASSISTANT LECTURER, Grade B (with an honours degree in zoology with subsidiary botany or a general degree in botany and zoology, and prepared to teach zoology to B.Sc. General and botany and zoology to G.C.E. advanced level standard) IN BIOLOGY—The Principal, Medway College of Technology, Horsted, Maidstone Road, Chatham, Kent.

BIOCHEMIST, Basic grade (graduate in chemistry or Associate or Graduate Member of the Royal Institute of Chemistry), IN THE DEPARTMENT OF PATHOLOGY—The Group Secretary, Queen Elizabeth Hospital for Children, Hackney Road, London, E.2.

BIOCHEMIST (Senior grade), to take charge of the East Riding Group Laboratory—The Hospital Secretary, Westwood Hospital, Beverley, East Yorkshire.

BIOLOGIST or BIOCHEMIST, to work in the United Birmingham Hospitals, Department of Clinical Endocrinology, on the immunological properties of pituitary hormones; and a **BIOCHEMIST** (Basic grade), to work on the determination of steroid hormones—The Director, Department of Clinical Endocrinology, Birmingham and Midland Hospital for Women, Showell Green Lane, Birmingham 11.

CHEMIST/ASSAYER (man or woman, preferably under 40, with a good honours degree in chemistry or equivalent professional qualification, and preferably with experience in inorganic analytical chemistry and a good knowledge of instrumental methods and/or electronics) IN THE MINES AND GEOLOGY DEPARTMENT, Government of Kenya, for duties which will include assaying and quantitative analysis of rocks, minerals and ores, and advising on metallurgical and chemical treatment problems connected with mineral extractions—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BOD.99/7/07/T.

GRADUATE ASSISTANT IN THE ENDOCRINE UNIT, to take part in biological, immunological and chemical techniques—The Chemical Pathologist, Hospital for Sick Children, Great Ormond Street, London, W.C.1.

GRADUATES IN CHEMISTRY OR METALLURGY, for fundamental studies of electro-deposition of metals and alloys—The Head of the Department of Metallurgy, Battersea College of Technology, London, S.W.11.

HEAD (preferably with a knowledge of the agricultural industry) OF THE DEPARTMENT CONCERNED WITH THE BIOCHEMISTRY OF ANIMAL NUTRITION—The Secretary, Rowett Research Institute, Bucksburn, Aberdeen.

LECTURER (with a good honours degree, and teaching experience, able to teach statistics to B.Sc. General Degree level, and preferably the ability to teach numerical analysis) TO TEACH PURE AND APPLIED MATHEMATICS AND STATISTICS to G.C.E. Advanced level and B.Sc. General Degree—The Clerk to the Governors, South-West Essex Technical College and School of Art, Forest Road, Walthamstow, London, E.17.

LECTURER (with an honours degree in electrical engineering and industrial experience) IN ELECTRICAL ENGINEERING with interests in Telecommunications—Northampton College of Advanced Technology, St. John Street, London, E.C.1.

RESEARCH WORKER (BIOCHEMIST or CHEMICAL PHARMACOLOGIST, with a Ph.D. or equivalent experience), to investigate the biochemical actions of drugs currently used in the treatment of mental illness—The Director of Clinical Research, Crichon Royal, Dumfries.

SENIOR LECTURERS or LECTURERS (with a first- or second-class honours degree, a thorough grounding in electrical engineering, experience in electrical power and machines, and/or electrical theory

and measurements) IN ELECTRICAL ENGINEERING, at the Royal Military College of Science, Shrivenham, Berks—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting D.627/0A.

SENIOR TECHNICIAN (fully conversant with general workshop practice and with practical electrical experience) IN THE DEPARTMENT OF X-RAY TECHNOLOGY, for duties which will include routine maintenance of X-ray apparatus—The Administrative Assistant, Churchill Hospital, Oxford.

SOIL CHEMIST (with a good honours degree in chemistry or agricultural science with postgraduate training or experience in soil science) in Sarawak, to take charge of the Soils Laboratory and to undertake soil and plant analyses—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BOD.68/24/08/T.

TECHNICAL ASSISTANT (preferably with some experience of standard histological techniques), for interesting and varied work in the Histology Department—The Administrative Officer, Nutritional Research Unit, Huntingdon.

FREEDOM IN ACADEMIC RESEARCH

IN a recent address, given in the University of Nottingham, Sir William Slater, secretary of the Agricultural Research Council, made a strong plea that universities should lead rather than follow contemporary thought, and in particular that they should be sufficiently independent financially to be able to allocate sufficient funds for research on lines of work entirely of their own choosing. Sir William was discussing the relative values of such research and of sponsored research, undertaken with the assistance of outside bodies, and he was firmly of the opinion that those carrying on research work in universities should have the freedom to decide whether they would pursue lines of work entirely of their own choosing, within the funds at their disposal, or whether they had problems to put to bodies, such as the Agricultural Research Council, for short-term assistance. The problem of course arises out of the extent to which the universities are now dependent on public funds, and how far, even with the University Grants Committee, it is possible for their independence from outside pressure to be fully maintained.

This was the subject of Prof. W. H. Linnell's address as chairman to the British Pharmaceutical Conference at Newcastle upon Tyne. Starting with the proposition that Britain's most valuable raw material is its young people, to whom education is of paramount importance if they are to develop the knowledge and powers of leadership which alone will ensure the country's survival as an important power, Dr. Linnell emphasized that the interdependence of education and research in science is fundamental. Further, whether or not Britain maintains her position in the world as a great power will depend, he said, largely on her research activities in the near future. These cannot exist unless we possess personnel capable of extending the boundaries of knowledge, and this, in its turn, depends on the education of the young and on some directive influence on their potential.

Against this background, and that of the economic threat developing behind the Iron Curtain, in consequence of the rapid expansion of scientific and technological education and research in the U.S.S.R., Dr. Linnell advanced his plea that academic freedom constitutes a fifth freedom to be set in importance along with President Roosevelt's four freedoms—freedom of speech and expression, freedom of worship, freedom from want, and freedom from fear. Moreover, powerful forces are working against academic freedom in many parts of the world, and these should be resisted at all costs. In particular, he referred to secrecy, especially in regard to publication of research. Secret work of any kind has no place in a university except during an emergency.

In establishing his thesis that our position in the world may well depend upon the fundamental research effort of the immediate future, Dr. Linnell followed in some respects Sir George Thomson's argument in his

presidential address to the British Association, deprecating the evaluation of research solely by its contribution to modern living. He was, however, more concerned with the educational aspect—both with the need for greater expenditure on education and with the question of quality, particularly that of an adequate general education, though he recognized that it might be necessary also to encourage an increasing number of students into scientific and technological fields. The colleges of technology as well as the universities have their part to play in providing an adequate body of workers capable of original thought and possessed by a burning desire to extend the frontiers of knowledge.

Given, however, an adequate supply of research workers of the requisite quality, the question of the distribution of the research effort of Britain remains. Even the balance between fundamental and applied research is not easy to determine, and while Dr. Linnell urged that the larger industrial organizations should accept some responsibility for fundamental research in appropriate fields, he did not go into the question of the distribution of research effort as between the universities, independent research institutions, the research associations, Government research stations or departments and industry itself. This question of distribution, however, is quite as important as what Dr. Linnell describes as the basic problem of how to plan our research effort without detriment to intellectual freedom, and indeed its wise handling could go far to remove many dangers to academic freedom. Apart from this, the question of distribution is related to that of the effective utilization of the results of research.

In emphasizing that while it is impossible to plan discovery, it is quite possible to plan for it, Dr. Linnell suggested that more could be done within the universities to ensure that the existing potential for research is utilized in projects that are really worth while. Research within the universities, it is true, serves at least two different, but allied, functions, and this is equally true of research in the colleges of technology, where perhaps expert guidance is particularly needed if they are to make a serious contribution to the research effort. Moreover, the educational objective—both in respect of the teacher and the students he is training—is the more readily achieved if the research effort is itself directed at some objective really worth while.

Dr. Linnell clearly recognizes the difficulty of supplying any such guidance from outside without trespassing on academic freedom, and the Committee on Science and Freedom has evidence enough of how easily academic freedom is infringed even in countries like Canada and Australia. Dr. Linnell's own suggestion is for the universities themselves to set up separate science committees for each scientific discipline to advise on all matters concerning research.

He visualizes such committees acting as clearing houses for ideas, with contacts with research associations and other bodies, and arranging opportunities for people working on similar projects to meet; his suggestion is essentially an extension of what is already being done by the Council for Scientific and Industrial Research and the Medical Research Council, though all the arrangements would be in the hands of the universities.

Nevertheless, if we are to make the best use of the limited resources of scientific man-power in Britain, as Dr. Linnell intends, the Minister for Science must play some part. This is as essential if sufficient financial resources are to be available for research as it is in securing that such man-power is not wasted for lack of either equipment or supporting technicians or through excessive overlapping. Co-ordination is probably best effected by such informal arrangements as the Research Councils are already establishing and the University Grants Committee may also seek to foster; but if public support on the scale visualized by Dr. Linnell is to be secured, the full influence of the Minister for Science and the Advisory Council on Scientific Policy will be needed.

This will be no less essential in the campaign of public education for which Dr. Linnell calls. The scientist himself has indeed an essential part to play in educating public opinion so as to secure adequate support for research, and so also have bodies such as the Parliamentary and Scientific Committee. Finance, however, is only a part of the problem, and in securing the most effective use of scientific and technical man-power, as is indicated by Sir Lindor Brown in a Sir David Russell Memorial Lecture delivered before the University of St. Andrews on March 9, 1960, scientists must themselves exert an important influence.

Under the title "The Perils of Leadership in Science"*, Sir Lindor discussed some problems which bear closely on the quality and effectiveness of university research, and his unusual approach directs attention to factors determining the utilization of trained scientific man-power which are sometimes overlooked. In the main, he is concerned with teachers and research workers in the experimental sciences and those near to them in interest and activity, and at the start he points out that the use of the military analogy in describing the technique of promoting scientific advance can be misleading. Rarely is it possible in scientific strategy to define an objective within the reach of a life-time, and very rarely is such an objective attained.

Sir Lindor Brown's thought runs on the lines of the Barlow Report on scientific staff, now largely forgotten, and he thinks that too little is made of the needs of the scientist for inspiration, and of the quality of a work of art that good scientific work possesses. Sir Edward Appleton, of course, has emphasized this aspect, but Sir Lindor discusses its bearing on funda-

mental research work, in which he suggests there are three major decisions of strategy to take: what to start, when to stop and where to go, and in that order. Leadership, he suggests, consists essentially in the supply of inspiration, and he is convinced that the British Isles still have a unique supply of original minds and can offer unique opportunities for their cultivation and development.

It is in regard to the starting of a project that the young research worker, he suggests, nearly always needs guidance, and that the real qualities of leadership of his science are fully tested only when, after the younger man has started work on his problem, he has an idea of his own. The treatment of that idea may make all the difference to the younger man's future career, and Sir Lindor stresses the importance of taking every care to avoid damaging what should be the most profitable feature of a scientist's life, namely, the free interchange of ideas and argument. Sympathy and imagination, however, are equally required in helping the young worker to deal with the second difficulty, that of knowing where to stop and when to publish his results. In many fields research is more or less a continuous process, and even the experienced worker does not find it easy to take alone the decision when to publish.

Sir Lindor was concerned to emphasize the necessity of publication to complete the research process, and while this has an important bearing on the question of secrecy and academic freedom, his remarks about the continuous nature of such research and the difficulty of setting a clear objective direct attention to an aspect that has to be considered in determining the distribution of our research effort on the broadest scale. It indicates one reason why the maximum of choice must be left to the research worker himself, and recent reports from the Council of Scientific and Industrial Research show that it is a difficulty of which the Council is deeply conscious. If only for the personal effects and the bearing of such decisions on the whole atmosphere in which work is done, as much flexibility as possible is clearly desirable. Enthusiasm once really dampened is seldom easily re-kindled.

The third aspect, that of deciding where to go, is closely related to the second. The attractive vistas continually opened up as work proceeds on a problem set a series of difficult decisions in which even the most experienced scientist may make the wrong choice. The opportunity for wise and enlightened leadership is unmistakable, but even so the leader may take an incorrect decision and the effect on his team may be disastrous unless the right atmosphere already exists. Space, facilities, adequate finance, freedom from petty worries, either domestic or administrative, adequate recognition, someone to give a measure of encouragement at more serious moments of frustration or despondency, perhaps also, as Sir Lindor Brown suggests, some alternative activity, as a little teaching, to stimulate the mind, all have a part to play; and if there is a leader whose wisdom and understanding have already won

* The Perils of Leadership in Science. By Prof. Sir Lindor Brown. (Sir David Russell Memorial Lecture No. 2, delivered before the University of St. Andrews at Queen's College, Dundee, 9 March, 1960.) Pp. 20. (London: Oxford University Press, 1960) 3s. 6d. net.

the confidence of his colleagues, the essential conditions should be there to ensure that creative work is not thwarted by the inevitable mistakes in human judgment. Seldom, he recognizes, can the head of the laboratory claim sufficiently detailed knowledge to give more than general advice to his colleagues on their scientific problems; but if in good time he can detect the faltering of genius, or an alternative activity of promise, and secure its adoption without causing resistance and revulsion, a laboratory director has discharged one of his most important functions.

Nothing is more important, however, in Sir Lindor Brown's address, than the stress he lays, in conclusion, upon the human demands made on leadership in scientific activity. It is a continuous process, intimately linked with that process of free discussion and criticism which is the essence of scientific advance, and Sir Lindor's own experience leads him to stress the importance of the research director himself working in the laboratory to maintain sympathy and close contact with his staff. He admits the desperate seriousness of the problem of time, but maintains unhesitatingly that to preserve our originality of approach, our capacity for unexpected discovery, and our unconventional freshness of ideas, in which we stand alone, we need leaders who will lead in the laboratory, leaders with sympathy and understanding for the man on the job and leaders with the humility of the true scientist.

That needed to be said, and should be marked in the universities and in Government departments and organizations as well as in industry. Unless those conditions are observed, we shall undoubtedly fail to make full use of whatever scientific and technological man-power is at our disposal, and above all in research. To ensure that such conditions are generally to be found is one of the most economic ways of expanding our existing research effort, but to achieve it may well demand some hard and constructive thinking about problems of administration. Sir Lindor is well aware of the increasing administrative burdens which are being placed on the heads of research units and departments in the universities, in the Government service and in industry, burdens which can scarcely be reduced to-day, however flexible our organization, except by sharing them more widely. That in turn requires a growing supply of scientists and technologists capable of assuming such responsibilities. From that point of view alone it is encouraging to note that in his presidential address to Section B (Chemistry) at the recent British Association meeting at Cardiff, Dr. James Taylor lent the weight of his own experience as a director of Imperial Chemical Industries, Ltd., to what Prof. T. L. Cottrell had said in his inaugural lecture at the University of Edinburgh last autumn as to the need for the universities to ensure that they gave their students not simply a good general education, with all that that implies as to an imaginative approach to human problems, but above all inculcated a critical and intellectual approach to whatever problems confronted them. The effective deploy-

ment of our limited resources for research and development demands indeed sound organization constantly kept under review by wise and imaginative administrators: it depends, in particular, on the quality of the man-power available, for the prosecution of research and for the handling of the myriad problems of co-ordination and co-operation, inspiration and guidance on which Sir Lindor Brown touched with vision and understanding.

THE STUDY OF SUB-ATOMIC PHENOMENA BY THE NUCLEAR EMULSION

The Study of Elementary Particles by the Photographic Method

An Account of the Principal Techniques and Discoveries illustrated by an Atlas of Photomicrographs. By C. F. Powell, P. H. Fowler and D. H. Perkins. Pp. xvi+669. (London and New York: Pergamon Press, 1959.) 250s. net.

THE study of sub-atomic phenomena, and in particular of the elementary particles, has been much aided by three techniques, the cloud chamber, the photographic emulsion, and the bubble chamber, by which the tracks of individual charged particles can be made visible. This volume is the third of a series designed to present carefully selected photographs of high technical quality to help students to acquire a better understanding of the physical principles involved in sub-atomic phenomena. In these volumes there are reproduced not only those photographs which have made history but also a sufficiently wide range of others to illustrate the power and limitation of the different techniques, and to serve as exercises in the recognition and interpretation of the nuclear phenomena produced by cosmic rays or artificially produced high-energy particles. The first volume, by the reviewer and J. G. Wilson, which appeared in 1952, and the second, by W. Gentner, H. Maier-Leibnitz and W. Bothe, published in 1954, were concerned with the application of the Wilson expansion chamber to cosmic rays and nuclear physics. The present volume covers the application of the photographic emulsion technique to the investigation of the elementary particles and cosmic rays. In common with the companion volumes, the photographs are central and the text is written around them, but unlike the previous volumes the text here is so extensive that the book has become a monumental work on the emulsion technique.

There are good reasons why the present time is opportune for such a work. The first reason is that with the advent of the bubble chamber and the production of beams of the new particles at the great accelerators, the period during which the emulsion technique has occupied a unique place in the study of the elementary particles is drawing to a close. The second reason is the growing confidence that, as the authors state in the preface, "most of the particles which play an important part at that level of penetration into the structure of matter which our present technical resources allow, have either been discovered, or their existence anticipated".

The nuclear emulsion makes possible the precise identification of most of the charged elementary

particles by virtue of its unusual power of discrimination and high stopping power. Its property of continuous sensitivity makes possible the accumulation of rare particles and 'events'. The emulsion is, however, not a very powerful technique for the study of the neutral unstable particles because of the lack of time correlation; and its chemical complexity can cause ambiguity in interpretation. The newly developed bubble chambers seem to combine most of the desirable features of both the nuclear emulsion and the Wilson chamber (apart from cost!), and, moreover, can operate at a speed appropriate to the rapid pulse-rate and high background of the great accelerators. Nevertheless, the nuclear emulsion technique still seems to be the technique most suited to the study of ultra-short-lived particles, in consequence of the extreme fineness of the photographic grain, and of certain aspects of the interaction of cosmic-ray particles of very great energies.

The book opens with a well-documented and illustrated history of the use of the photographic emulsion in nuclear physics and the steps which led to the production of the nuclear emulsion. There follow excellent sections on the basic technical features of emulsions, the range-energy relations, and the measurement of specific ionization and scattering, quantities of considerable importance in the emulsion technique. These sections are beautifully written and illustrated, and will be of great value in the training of research workers. Most of the rest of the book is concerned with the elementary particles, electrons and photons, μ -mesons, π -mesons, K -mesons, hyperons, protons and antiprotons; but there are also quite long sections devoted to hypernuclei, interactions in the energy-range 10^2 - 10^3 MeV., and heavy nuclei in the primary cosmic radiation. Fundamental discoveries made by use of the technique, for example, the π - and τ -mesons, heavy primaries and hypernuclei, are fully described, and with the original photographs serve as a reminder of the achievements of British physicists in the exciting early post-war years. In all there are 190 plates, superbly chosen and reproduced, and numerous excellent figures to illustrate the text. The text is a clear account of many of the technical aspects of the use of nuclear emulsion in the high-energy field and of modern high-energy nuclear physics. There are a few small errors, but on the whole the book is singularly free from error.

This magnificent volume can be most warmly recommended to anyone interested in nuclear physics, and is a worthy tribute to the part played by the nuclear emulsion technique in the study of the elementary particles. It is also a brilliant tribute to the research school of which the authors are distinguished members.

G. D. ROCHESTER

ORIGIN AND DEVELOPMENT OF LIFE

You and the Universe

By Dr. N. J. Berrill. Pp. viii + 215. (London: Dobson Books, Ltd., 1959.) 18s. net.

PROF. N. J. BERRILL has produced a tantalizing book. In it he sets out to show the origin of life, the way it has developed and the place it holds in an evolving universe.

The task is not beyond him and many readers would agree that, with impeccable prose, crystal-clear thinking and considerable scholarship, in this volume he leaves a stimulating picture of the one-ness of life and the whole-ness of the universe.

The theme is developed in an evolutionary sequence to show how scientific knowledge and thought eventually widen out to find common ground with spiritual insight and belief. Yet as soon as the author reaches a point where a philosophy which is spiritually satisfying might emerge, he breaks off as if at the end of his tether.

The result is a book which, because of the almost poetic style in which the biological and astronomical material is presented, could be hard going for the general reader whose learning is now adjusted to the superlative illustrative diagrams, photographs and models used by the B.B.C. in its current research series on television. The student with some knowledge of biology will be left somewhat frustrated because the end leads to unsatisfying whimpers rather than a statement of sustaining revelations and beliefs.

This is a disappointment, because, without question, Berrill has out-of-the-ordinary gifts in presenting ideas through the written word. He should use them to finish this book.

Whether "You and the Universe" is improved by the extracts from Walt Whitman which launch each chapter will depend on taste. Certainly, the physical presentation will not be to everyone's liking.

T. H. HAWKINS

STRAIGHT-LINE DATA ANALYSIS

Analysis of Straight-Line Data

By Prof. Forman S. Acton. (Wiley Publication in Applied Statistics.) Pp. xiii + 267. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 72s. net.

PROF. ACTON demonstrates that a book the object of which is utilitarian can also be attractive to the reader, perhaps mainly because of the freshness of his style and his insistence on keeping close to real experimental problems. He is interested in answering the questions that experimenters need to ask, and early makes plain his attitude by stating: "If we waited for all the epsilons and deltas to be supplied before we used techniques that statistical common sense suggests, we would be technical paupers". His second chapter is probably the best systematic account yet available of the classical problem of simple regression, with its many ramifications in respect of errors and limits for different estimates; it should be read by all who imagine that they have nothing more to learn about these techniques.

In another major chapter, the frequently evaded topic of regression with both variates subject to error is discussed, and the similarities and differences between various practical situations are considered. The methods proposed owe much to Tukey, but Acton's own contribution is evident. Acton's presentation is distinctive among statistical texts for the blunt common sense of his recognition that the duty of the practising statistician is not simply to construct models, to test hypotheses, or to make decisions in accordance with abstract principles; he must interpret numerical data in whatever manner may be most appropriate to their source and their intended

use, recognizing the imperfections of these data but seldom admitting total defeat in his efforts at rational analysis. The writing is interspersed with remarks of refreshing directness and practicality: "... if our purpose is to analyse data realistically, we must face the anomalous situations which all too frequently occur rather than pretend that they do not exist. If the information is not precise, it is usually necessary to make some subjective judgments, and the best place to make them is where they have the least influence on the information extracted. If the assumptions turn out to be wildly different from the physical facts, the conclusions will be bad too, but the fault will be with the person who made the assumptions—not with the method of analysis".

Chapters on analysis of variance and on orthogonal polynomials are more conventional in pattern, though still containing ideas that too many authors neglect. The account of multiple comparison procedures is much condensed; some may wish that the author had brought his admirable critical sense to bear on this complex of methods, instead of simply accepting one, even though that one is possibly among the most useful. Later chapters attempt little more than to direct attention to aspects of regression on which further research is needed. Although Prof. Acton disclaims all intention of writing a text for class use, neither students nor their teachers could fail to gain from his book; both the novelty of its content and a style of writing that is vivid, unafraid of the telling metaphor or colloquialism, yet never obscure or verbose, should commend it both for its own sake and as an example.

D. J. FINNEY

THE PARANORMAL: A FRENCH VIEW

Treatise on Parapsychology

Essay on the Scientific Interpretation of the Human Phenomena known as 'Supernatural'. By René Sudre. Translated by C. E. Green. Pp. 412. (London: George Allen and Unwin, Ltd., 1960.) 35s. net.

THIS book is an attempt to provide the general reader with a survey of the whole field of psychical research from early times until the present day. It was first published in Paris in 1956, and its plan was clearly to allow other than English-speaking people to know something of what has been done in this field both in Great Britain and the United States, where the general attitude towards parapsychology is not the same as in France, Italy and other countries on the European continent.

M. Sudre is well equipped for the task he has set himself, for he has long been one of the most distinguished exponents of that point of view common in France early in this century but now being superseded. Closely associated for many years with Prof. Richet, Dr. Geley and others connected with the Institut Métapsychique in Paris, he has seen much and his attitude is typical of this group of French inquirers, being keenly critical of any theories savouring of spiritism, while at the same time somewhat credulous as to the reality of the phenomena to be interpreted.

After a brief historical survey the author proceeds to a discussion of the phenomena, linking them with sudden changes in what he calls the 'psychological

personality', an alteration he terms 'protopopesis'. He then passes to a consideration of telepathy, clairvoyance ('metagnomy') and the relation of a supposed psychic fluid to mesmerism, radiations and telergy. From consideration of this supposed action at a distance he then goes on to discuss 'teleplasty', or the objectivization of forms, and concludes his study by dealing with spontaneous cases, haunts, mysterious behaviour in animals and phenomena claimed by spiritists to be striking indications of survival after death.

M. Sudre's own opinions are anchored to his faith in the reality of the so-called physical phenomena. He believes in materialization, even going so far as to credit the partial dematerialization of mediums' bodies in séances: he believes in psychic photography and has many good things to say about such dubious mediums as Guzik, Kluski, Florence Cook, Reese, Kahn and even Kraus, although he does not give Kraus's name nor let the reader know that this person confessed to his frauds in an unpublished memoir. He even maintains that the phenomena at Borley Rectory were 'incontestably genuine' and this in spite of incontrovertible evidence to the contrary.

Since the author is convinced that certain human beings are endowed with these astonishing faculties, he finds the spiritistic explanation of little value and the evidence for survival, so painfully collected by the British and the Americans, he brushes aside as simply examples of 'perceptive metagnomy' and 'collective psychism', while at the same time he defends the theory that the so-called telepathic apparitions are objective and that the hallucinatory nature of these experiences cannot be maintained.

The book is well produced and translated, although it lacks an index of subjects, and some of the mistakes and misprints in the French edition (for example 'Mac-Aba' for 'MacNab') have been carried over into the English version, where more care in the standardization of references would have improved the book.

E. J. DINGWALL

A CENTURY OF NAVAL ARCHITECTURE

The Institution of Naval Architects, 1860-1960

An Historical Survey of the Institution's Transactions and Activities over 100 Years. By K. C. Barnaby. Pp. 645+11 plates. (London: The Royal Institution of Naval Architects, 1960. Published in association with George Allen and Unwin, Ltd.) 105s. net.

IN 1791 a laudable attempt was made to found a 'Society for the Improvement of Naval Architecture', but the venture was premature and therefore short-lived. By 1860, however, sail and steam were in competition, iron was challenging timber as a ship-building material, the mercantile marine was expanding rapidly and an era of swift technical advancement had begun. In these circumstances, the Institution of Naval Architects was brought into being by a small group of founder-members. It has been stated that the history of the Institution is the history of naval architecture, and the Institution, now 100 years old, has been honoured by its new title of the 'Royal Institution of Naval Architects' and has celebrated its centenary by meetings in London and by the production of this excellent and fascinating volume.

The preparation of "The Institution of Naval Architects—an Historical Survey" was entrusted to Mr. K. C. Barnaby, himself a naval architect of high repute, and he has accomplished his task with extraordinary success. He writes with lucidity, perspicacity and with the saving grace of humour. His method is to review each volume of the Institution's *Transactions*, reminding the reader of the existing state of knowledge and summarizing each paper with admirable brevity. Such a course might well be hazardous in less-skilful hands, but Mr. Barnaby is a master of his subject and is never guilty of airing either hindsight or superior knowledge. He can be forthright without being rude, and he can be complimentary without being condescending. Occasionally he is devastating, as when he describes one early paper, by a gallant admiral pontificating on warship design, as "a farrago of nonsense".

A perusal of these pages gives a clear and connected account of the advances in naval architecture and marine engineering since 1860. One reflects ruefully that a final solution is rare in applied science, for the problems of resistance, strength, stability, rolling and steering discussed in the earliest volumes are still, although in modified forms, the subjects of continuing investigations. One point worthy of note is that in discussion our forefathers were frank to the point of rudeness. Our present-day discussions of technical papers are colourless and stilted by comparison.

A centenary is perhaps as suitable an occasion for taking stock as any other. The Institution has tried to improve the status and the training of naval architects and has always been active in furthering efforts to improve the design, construction and safety of ships. But merchant ships, although they may well continue to provide the cheapest form of transport, are now subject to forms of competition undreamt of by the founders of the Institution. With warships the changes are no less marked, as, for example, the aircraft carrier supplants the battleship.

Research in naval architecture has, until recent times, been left to private enterprise and not heavily supported by government bodies or trade associations. The volume records a hundred years of technical advance and the next centenary will, one hopes, see accelerated progress in technical developments, if Great Britain is to retain its position of eminence in shipbuilding.

J. F. C. CONN

GROWING UP

Growing up in Newcastle upon Tyne

A Continuing Study of Health and Illness in Young Children within their Families. By F. J. W. Miller, S. D. M. Court, W. S. Walton and E. G. Knox. Pp. xxi+369+9 plates. (London: Oxford University Press, 1960. Published for the Nuffield Foundation.) 25s. net.

THIS book is the second volume of an inquiry into the pattern and extent of illness during childhood in Newcastle upon Tyne. The first volume ("A Thousand Families in Newcastle-on-Tyne"), deals with the first year of life. The present volume is concerned with the age group of 1-5 years.

The investigation is continuing until 1962, when the children will be fifteen, and a third volume will cover the school years.

The study is based on observations during visits to the homes, by health visitors and doctors, on all infants born in Newcastle upon Tyne during May 1-June 30, 1947. The original 1,142 children have now shrunk by removals, withdrawals and deaths to 847.

The work, inspired by the late Sir James Spence, is an attempt to discover the occurrence and natural history of illness as they occur in families and to find out how the pattern and outcome of disease are influenced by the child's environment. Our knowledge of child ailments has hitherto been based on vital statistics, hospital attendances and the records of general practitioners. It shows how incomplete such knowledge can be, for in nearly half the illnesses the doctor was not called in.

The book follows the same pattern as the earlier one. A section is devoted to the environment of the child, under the headings: housing, family, and medical care. The housing, as one would expect in an industrialized city, left much to be desired, and many houses and flats were in a dilapidated condition and many families live in overcrowded conditions. About one quarter of the mothers were employed in whole- or part-time work.

After a preliminary discussion of the pattern of the illness in the first five years of life the authors go on to describe in detail the diseases group by group. It is shown that infective illness still causes 82 per cent of all morbidity in the first five years. Respiratory diseases ranging from heavy colds to pneumonias form nearly two-thirds of all infective illnesses. Fortunately, fatal illness is uncommon after the first year of life. The incidence of bronchitis was ten times higher in the families of labourers and unskilled workers than in professional families.

Tuberculous infection has steadily diminished in the period under review. In 1947, 85 deaths occurred in children under 15 years. By 1954 the total had fallen to four. As judged by tuberculin jelly tests, 7 per cent of the children had become infected by 5 years of age. This is a striking change as compared with the proportion of positive reactors twenty years ago.

One section of the book is devoted to conditions which are considered to be associated with the social environment. Alimentary infections occurred most frequently in families where there was deficient care of the child, or where the family was living in a small house with low rents and especially in tenanted and mouse-infected property in the older parts of the city.

Accidents, which are now one of the principal causes of death in childhood, comprise the other large group associated with the environment. Many of the home accidents such as burns, scalds and the swallowing of poisons are preventable. Accidents were found to be more prevalent in families where the quality of the mother's care was unsatisfactory.

In the final chapter the authors conclude that the health of the children and the outcome of diseases are closely related to family environment.

The statistical data are presented in a series of useful appendixes.

The book is a valuable addition to the knowledge of the pattern of childhood diseases in a community and of socio-economic factors which influence them. It should prove valuable to doctors working in family practice, preventive medicine and hospitals, as well as to health visitors and others who are responsible for the welfare of children.

G. H. NEWNS

Check-List of Birds of the World

Vol. 9. Edited by Ernst Mayr and James C. Greenway, Jr. (A Continuation of the Work of James L. Peters.) Pp. xii+506. (Cambridge, Mass.: Museum of Comparative Zoology; Copenhagen: Zoological Museum, 1960.) 7.50 dollars.

THIS is the basic modern work in systematic ornithology and was planned for fifteen volumes. Of these, Volumes 1-7 appeared in the period 1931-1951 and covered all the non-passerine birds and a few families of passerines. The death of Peters in 1952, with only a little more material ready in manuscript, made new arrangements necessary for completion. The editors appointed by the Museum of Comparative Zoology at Harvard are E. Mayr and J. C. Greenway, jun., and they have proceeded on the plan of apportioning the groups among selected specialists in America and Europe. This should speed up the issue of the remaining volumes, which will appear when ready and not in numerical sequence.

Volume 9 is thus the first to appear under the new arrangements. It covers a dozen passerine families of varying distribution—some cosmopolitan (for example, swallows), some purely Old World (bulbuls, etc.), some purely New World (for example, mockingbirds), and some very restricted (such as the vangas, peculiar to Madagascar). Each familial section has its own author, and other systematists who have read the manuscript in a consultative capacity are named in addition. The information given consists of the scientific names (with references) of each species and each sub-species thereof, and the distribution of each form.

The resumption of publication of this important work is most welcome, and on the new co-operative basis of authorship one may hope for early completion. One may then look forward to revised editions of some of the earlier volumes which are out of print as well as in parts out of date.

LANDSBOROUGH THOMSON

Institut National des Sciences et Techniques Nucléaires

Symposium de Métallurgie Spéciale organisé à Saclay les 27 et 28 Juin 1957 par le Département de Métallurgie et de Chimie Appliquée. Pp. iv+128. (Gif-sur-Yvette (S.-et-O.): Centre d'Études Nucléaires de Saclay; Paris: Presses Universitaires de France, 1958.) n.p.

AS the title suggests, this symposium concerned particular problems in nuclear metallurgy. Certain of the papers are transcriptions of previous published work. Naturally enough, the majority originate in France, but there are four outside contributions, from Holland, Sweden and Great Britain.

The main topic of the symposium is occupied with allotropic transformations, recrystallization and textures which result.

The transformations in uranium and zirconium and their various alloys are discussed from several aspects. One paper makes a comparison between uranium and iron.

The work on recrystallization and polygonization is treated from a variety of angles, and examples are illustrated from magnesium, aluminium, zirconium, cobalt and titanium, or alloys based on these metals.

As usual, some beautiful micrographs are reproduced, particularly those by Prof. P. Lacombe on polygonization in uranium, and the examination of alpha structures in uranium by Mme. Lehmann and

H. Aubert. There is an interesting report on mechanical properties of magnesium-zirconium alloys which is relevant to British work soon to be reported by the Institute of Metals.

The discussion is included at the end of each paper, and the proceedings commence and terminate with the speeches of welcome and conclusion presented at the time.

C. R. TOTTLE

Sonderausschuss Radioaktivität

Bundesrepublik Deutschland, Zweiter Bericht, März 1959. Pp. 117. (Stuttgart: Georg Thieme Verlag, 1959.) 12.60 D.M.

AN impressive organization for measuring the contamination by radioactive materials has been set up in West Germany. The reported data for 1958 show a wealth of measurements of the concentration in the air near the surface, in water from different sources, in the soil, in plants, animals and bones of humans. Comparison of the data for 1958 with those of previous years shows no significant increase. An attempt to predict the increase in fall-out if testing of nuclear weapons is either discontinued or if it proceeds at the rate of the year under review indicates that substantial increases are to be expected. A survey of the results of the German film protection service shows that nearly 10 per cent of persons engaged in work connected with ionizing radiation receive doses of more than 0.4 r. per month. In future reports an estimate of the amounts of radiation received by patients in hospitals would complete an otherwise admirable survey. The data are set out in great detail in a large number of well-designed tables.

S. R. PELO

Linear and Stereoregular Addition Polymers

Polymerization with Controlled Propagation. By Norman G. Gaylord and Herman F. Mark. (Polymer Reviews, Vol. 2.) Pp. x+571. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1959.) 135s.

THE recent discovery of methods of synthesis of sterically regulated polymers is not only of fundamental scientific interest but also has opened up possibilities for far-reaching commercial application. Since Zeigler's spectacular discovery of the catalysts for the low-pressure polymerization of ethylene, and Natta's brilliant syntheses of stereoregular hydrocarbon polymers, an immense amount of research has been carried out during the past six years in scientific and industrial laboratories in Europe, the United States and Asia. This book summarizes systematically publications up to February, 1959, and also correlates the various characteristic features of the new processes. With the avalanche of new work being published it was a very noble task for the authors to attempt such a review. Much of the newer work is contained in an enormous number of patents, and since these still remain the most abundant source of information the chapter summarizing some 500 patent examples is one of the most valuable in the book.

While much more remains to be discovered about the mechanism of Zeigler catalysis and the nature of stereospecific polymerization, this book is the best source of information available. The authors have done a great service to polymer chemists in presenting a comprehensive and authoritative source of information on this new branch of polymer science.

C. E. H. BAWN

SCIENCE AND SOCIAL ORGANIZATION*

By SIR CHARLES GOODEVE, F.R.S.

THE scientific method has been as successful in helping in the operations of industry and civil government as it has in the military field; and there is also a growing amount of interest in a field which may be called 'social organization'. In this field, which is primarily a responsibility of government, the needs and the opportunities are great.

Scientists are repeatedly challenged by the accusation that they have been responsible for altering the lives of people and increasing their power to destroy one another, and yet have left most of the social problems so produced to others to solve. The advances of civilization arising from progress in science and technology have increased the extent of the interactions between what one person does and what another does or can do. These interactions require control, require social organization; but our knowledge of social interactions, and consequently our social organization, both lag behind.

Despite the encouragement of bodies such as the British and the American Associations for the Advancement of Science, scientists generally are, for a variety of reasons, reluctant to respond to this challenge. The objects and rules of social organization are substantially linked to moral issues, and science would not presume to replace faith or other human sources of principles in deciding these issues. Individual scientists, while confident that they can see moral issues as clearly as anyone, are often frightened of appearing unsophisticated or naive if they intrude into the deep field of philosophy. They might even fear that they would have to relax the discipline of their scientific method; the controlled experiment, so fundamental to the scientific method, can rarely be relied upon in this field.

Similar fears were present when scientists began to enter the field of operations. However, confidence has grown through success, not only in solving particular problems, but also often simply by helping management to clarify their objectives and to define their terms (in the light of the objectives). Also scientists have taught management not just to measure but to subject their measurements, both in the taking and in the interpretation, to the rigorous methods developed by science. Operational research workers therefore have less excuse than other scientists for avoiding the study of social problems. They have not avoided them altogether, but they could do more.

The social sciences have made important advances in recent years, but these have been mostly of a qualitative nature. However, it is rapidly becoming possible to determine fairly accurately what people think and want and do. The science of 'attitude and

behaviour surveys' has reached a stage such that governments now have a powerful tool to help them in their job of social organization. (By comparison, the referendum or town poll is very inaccurate and will become obsolete as soon as people learn this.)

Almost every operational research study has the difficult initial task of finding and stating the objective or the objectives; the solution of this is often in itself of great value to management. What is the objective of social policy, of social organization? The answer is, of course, more than just to control the interactions between people, more than just to raise the standard of living. Social policy has been a subject of infinite discussion since civilization began. Jeremy Bentham, the great English philosopher, was one of the first to attempt a precise definition with his proposed social policy: "what serves the greatest happiness of the greatest number".

It should help to clarify the objective if we could define some terms in a manner in which they can be measured and, with considerable hesitation, such an attempt is made here. People have wants or desires known to themselves which can be defined as the basis of motivation; their decisions will be generally in the direction of satisfying these wants. The extent to which material wants are satisfied is, of course, the 'standard of living', but this quantity is measurable only in respect of people living near the subsistence-level, and then only in a rather arbitrary way. For an increasing number of more affluent people, a much more comprehensive meaning of the word 'wants' is required—one to include those arising from psychological, spiritual and any other human source. It must also include a promise for the future and a reasonable insurance against sorrows and fears. Sometimes the expression 'standard of life' is used to indicate the extent to which all types of wants are satisfied. These comprehensive wants are, of course, impossible to measure directly, but their total is the basis of one important type of human action—migration.

Let us consider first two clearly specified groups of people, between which there is complete freedom to migrate. These groups may be specified geographically or by profession or in other ways. If there is a net migration towards, say, the second group, then the conditions under which that group lives, including its social organization, has a greater attraction, a greater drawing power than has the first. Let us associate with each group a quantity to represent the attraction and designate this quantity by the Greek word 'eudemony' (eudæ-mony).

To a scientist, quantities or properties are either 'intensive', such as temperature and pressure, or 'extensive', such as volume or length (the total being the sum of the parts). Eudemony, as here used, is

* Closing address at the Second International Conference on Operational Research, Aix-en-Provence, September 5-9.

clearly an intensive property, and furthermore it has all the characteristics of a potential, a sub-group of intensive properties. This means that it should be measurable in the same manner as other potentials, that is, by the spontaneous movement of the associated extensive quantity. Just as the comparative temperature of two bodies is determined by the direction of movement of heat, when restrictions or influences on its flow are absent, so the comparative eudemony of two groups of people can be determined by the direction of migration; this will tend to be from the region of lower eudemony to the one of higher.

Most actual migrations are not altogether free, and in addition are influenced by lack of knowledge or are biased by inertia or physical obstacles such as cost. For accuracy, one should carry out a controlled test in which representative samples of each group were exchanged and later the return migration studied. Where this is impracticable, perhaps the simulation techniques of operational research could be used. At all events, the influences due to ignorance or the special obstacles which cause actual migration to deviate from that of free conditions can usually be identified and allowed for.

These restrictions and influences should not weaken our confidence in the relationship between eudemony and migration; the impossibility of carrying out the frictionless Carnot cycle does not alter our confidence in defining and measuring temperature. Indeed, this parallel situation may encourage us to go further and to define the difference in the eudemony of two regions quantitatively as the influence or bias that would deliberately have to be put in to equalize the two return migrations in a controlled test. This influence could be put in by, for example, giving a monetary compensation to the sample that would go to the region of lower eudemony.

Essentially, what we have done is to define a property, the 'eudemony', of a group of people in a social system in terms of a measurable quantity, net migration. This concept of eudemony will require further analysis, but it will be generally agreed that it is related to the satisfaction or fulfilment of wants. Indeed, one can get a somewhat satisfactory physical picture of eudemony by considering it as the ratio of the satisfied to the unsatisfied wants. The acceptance of this latter picture is, however, not essential to the main conclusion, namely, that it is possible to measure the size of this property, because it is a potential, even though its components cannot be measured.

By the choice of the word 'eudemony' we are touching on the field of philosophy: Aristotle used this word to mean happiness through the satisfaction of all types of wants, with special emphasis on the non-material wants. However, it is to be emphasized that we are concerned here only with studying human behaviour and not with moral issues, not with whether the wants people feel are the right ones or not.

This hypothesis can be tested immediately against one's own intuitive ideas arising from the consideration of particular cases. Some cases will fit, some may not. Those scientists who have been brought up in the approach of thermodynamics and kinetics, of forces, equilibria and rates of change, may be more readily able to accept this than others. Most, however, will agree that the argument underlines the importance of freedom to migrate if one is ever to achieve an

objective meaning to 'standard of life' or its associated quantity, eudemony.

In attempting to pull out a basic hypothesis from such a complex thing as life, one can scarcely expect to avoid some limitations or qualifications. A full analysis of these cannot be made here; but some important ones should be dealt with. I have defined eudemony as a property of a 'clearly specified group of people', but obviously it is necessary that there be a reasonable degree of similarity between the composition of the groups; if not, migration would need to be analysed in terms of sub-groups. We could not easily compare the eudemony of a group of Jamaicans in Kingston with a group of Englishmen in Birmingham, but we could with another group of Jamaicans in Birmingham. It would become practically meaningless to try to compare the eudemony of two individuals; but of course, it is part of the hypothesis that any one individual in a group can examine the eudemony of his present circumstances in relation to that of any other possible set of circumstances.

So far, the definition has been related to groups existing at one period of time, so that two-way migration is possible. However, we have already at hand a reasonable way of overcoming this limitation. For example, should a government wish to know whether a proposed change in the social organization will increase or decrease the eudemony of a particular group, then the attitude and behaviour survey techniques referred to above can provide a reliable answer in most cases, because these techniques can predict the effect of the change on migration.

An increase in eudemony could by itself be used as a basis for social policy; but, if used alone, progress would be very slow. In history it is the 'reformer', the man with vision for the future of mankind, who is the initiator of most social progress. However, each man of vision has strong, highly individual and often conflicting views as to what people should want, as to what should constitute a high standard of life. The attitude of the group, while objective, suffers from relative conservatism and ignorance.

Social progress requires the existence of the reformer, but if he is to succeed he must do two things: get the support of the knowledge of the specialists responsible for studying particular problems, and get his ideas of wants accepted by the people of the group. This means that he should continuously measure his ideas for any change in social policy against the effects of such a change on migration. By thus narrowing the gap of controversy, social progress may be facilitated.

The above analysis of an objective of social policy has been chosen in the hope that, among scientists, interest may be stimulated in the field of social organization. The need for such interest is very great. Could we help by analysing the systems used in choosing our leaders, by analysing further the methods of decision-taking in groups of people? Could we measure the 'democratic' content of a particular system of government, perhaps by determining the extent to which considerations of eudemony influence the policy of that government? If so, we might bring the word 'democratic' out of the realms of emotional politics into clearer focus. These are bold targets, but boldness and courage are needed if we are to bring social organization up to the standard required to-day.

AEROBIOLOGY AND MEDICINE

THE pioneer of aerobiology in the service of medicine was C. H. Blackley, a medical practitioner living in Manchester and a sufferer from hayfever, whose book, published in 1873¹, was a model of scientific method and is now indeed a classic. Blackley's countrymen were ultimately converted to his view that hayfever could beyond doubt be produced by inhaling pollen, but it was in the United States that the need for botanical collaboration in solving the medical problems arising from the inhalation of plant spores was first realized: and by 1940 the Americans had established an undoubted lead in this field. The extent to which knowledge of the botanical aspects of allergy has been advanced in Britain since that date was illustrated in the symposium held by Section K (Botany) of the British Association meeting at Cardiff entitled "Botanical Aspects of Allergy".

Dr. D. A. Williams, physician to the Asthma and Allergy Research Unit at Cardiff, set the stage for subsequent speakers. He recalled that the word allergy, meaning a different or altered reaction, was first coined in 1906, and that the two allergic diseases in which pollen and fungus spores play an important part are hayfever and asthma. Hayfever affects some 0.5 per cent of the population. It is entirely an allergic disease, due to pollen, in the main to grass pollen, and some 30-40 per cent of grass-pollen hayfever patients also have pollen asthma. Tree pollen, in particular birch, ash, elm and in some districts, plane, can cause quite severe hayfever and asthma, but it accounts for only a small percentage of hayfever patients; and the pollen grains of herbs other than grasses appear to be relatively unimportant. Asthma affects some 1.0 per cent of the population, and frequent incapacity occurs in some 15 per cent of asthmatics: its causes are only partially understood. The main causes are infections (colds) in the upper air passages, psychological factors and extrinsic allergens (inhalants or organic dusts, and also, but less frequently, foods).

Recent advances in our knowledge of the aetiology of inhalant allergy are almost all linked up with research on plant spores. Thus the clinical investigation of certain types of fungus spore as allergens has followed the lines suggested by the census (centred on Cardiff and referred to here) of culturable moulds in the air over Great Britain: some 5 per cent of asthmatics have been found to have asthma caused by such spores; the most abundant single type, *Cladosporium*, is also (among fungus spores) the commonest cause of asthma, which in this instance is often severe and persistent in summer. Less common, but accepted causes of summer asthma, are *Botrytis* and *Alternaria*. Apart from these common constituents of the aerospora, *Cladosporium fulvum* has long been known to cause allergic symptoms in those who work in greenhouses; and *Aspergillus fumigatus* has recently been shown in London to cause, not infrequently, quite severe asthma. Many other fungal spores are capable of producing asthma, but their exact medical importance awaits investigation.

Mr. H. A. Hyde (National Museum of Wales, Cardiff; honorary director of botanical research at

the Asthma and Allergy Research Unit) reviewed the results of aerobiological research in the interest of medicine. When the investigation of plant spores in the air over Great Britain was first contemplated in 1941, no exact information existed on the kinds of pollen (or other spores) occurring in the air, or even of their dates of liberation, still less their relative abundance. Systematic trapping by the so-called gravity slide method began at Cardiff (where it has continued without a break since January 1942) and has since been extended in most instances for a period of a year or more to 15 other stations from the Scillies to Aberdeen and situated in urban, rural, coastal, mountain and maritime situations.

The order in which the various types of pollen appear in significant numbers in the air of Great Britain varies little from year to year; though it may be telescoped or drawn out according to weather. The most abundant types on the average probably throughout the country are four kinds of tree (elm, ash, birch and oak), three kinds of 'weed' (non-gramineous herbaceous plants), namely, plantain, *Rumex* (sorrel and dock), and nettle, and above all grasses. Of these, grass pollen is the least variable in its period of prevalence: its concentration, as measured by the Hirst trap, is almost negligible (a few grains per cubic metre) until late May, after which it soars rapidly to mean 24 hr. values of 500/m.³ or more by or before mid-June, and then falls more or less rapidly (except locally in the neighbourhood of late-flowering grasses) to a low figure by August. On sunny days during the peak period the 'spot' count rises late every afternoon in central Cardiff to between 1,000 and 1,750 grains/m.³; though in sunless weather it may scarcely rise above zero. The grass pollen 'season' is probably more or less equally severe over the whole of the lowlands of England and Wales, but less in the mountains and of course increasingly less as one goes out to sea. Strictly indoor air (with doors and windows tightly closed) even on a sunny day in the lowlands at the height of the season contains little pollen. The inhalation of grass pollen in quantity can largely be avoided by following simple rules based on the present knowledge of its variation according to time, place and weather.

Tree pollens vary in their abundance very widely from year to year, so reducing the probability of sensitization to them. Nettle pollen is on the average numerically more abundant than any other kind except that of grasses, and, like its near relative pellitory-of-the-wall in southern Europe, it may prove to be an important allergen.

Study of the fungus aerospora in Britain began with a (gravity slide) census of *Alternaria* spores at Cardiff 1942-43: they were found to be present in numbers which suggested that *Alternaria* allergy might well occur in the human population. Further observations (by means of culture plates) followed from 1947 onwards.

Examination of the complete fungus aerospora by means of the Hirst trap, from 1957 onwards, has confirmed the findings of Drs. Gregory and Hirst at Rothamsted on its composition and has shown that

on average the fungus spores are 60–70 times as numerous as pollen grains. But this figure does not indicate their relative importance as allergens: the volumes of the various types of grain or spore must also be taken into account. When this is done and the various kinds are arranged in order of bulk abundance, that is, the volume of the spore (in μ^3) per unit volume of air, it is found that present views on the importance of grass pollen (which comes at the top of the list) and *Cladosporium* spores (which come second) are confirmed, and several kinds of pollen and fungus spores, all of them known or strongly suspected to act as allergens in Great Britain, come fairly high. Ascospores and basidiospores (both as yet mainly undifferentiated) come respectively third and fourth. It may well be that the latter will prove, as Gregory and Hirst have suggested, to merit serious consideration as allergens.

Principles are emerging from the work on inhalant allergens. Some types of plant spore are inherently more likely to evoke symptoms than others: among flowering plants high allergenicity is confined to a small number of families; we cannot yet say how it is distributed among the fungi. Other things being equal, the most abundant types of spore are the most likely to be important as allergens. Some kinds of spore are present in the air in effective concentration year after year; these are much more likely to produce sensitization than those the concentrations of which become high at longer and less regular intervals. When the concentrations of different kinds of spore are being compared, numbers should be weighted for size.

Dr. Merfyn Richards (Beecham Laboratories, Ltd.) discussed the mould spore population of the air. He said that work, by means of culture plate techniques, on the mould spores present in the air has enabled a picture to be drawn of the relative quantitative importance of the various kinds, and of when and where they occur. Surprisingly, perhaps, but fortunately for the allergist and the allergic individual, there are relatively few genera of moulds of great numerical importance in the air. At Cardiff more than 80 per cent of the colonies grown from trapped spores are identifiable. Of these 95 per cent or more are assigned to only a dozen genera; during three years, 1951–53, *Cladosporium* alone made up nearly half, and with *Penicillium* and *Pullularia* nearly three-quarters of the identified catch.

Several of these moulds have a 'season' of higher incidence. *Cladosporium*, *Epicoccum*, *Alternaria* and *Botrytis* occur in much higher numbers in the summer months than at other times. *Penicillium*, on the other hand, seems to be present in the same sort of quantities the year round.

The same kinds of mould spores occur in quantity at seven other centres up and down Great Britain, but *Cladosporium* shows a much greater incidence in rural areas, while higher counts of *Penicillium* are associated with the big cities.

The same mould genera which are most important numerically in the air over Britain are also the most important elsewhere in Europe, North and South America and New Zealand. In warmer climates than Britain, *Alternaria* assumes greater importance, and in places, for example the central United States, vies with *Cladosporium* for predominance.

The spores produced and released from the moulds growing in damp houses, cellars, barns, haylofts, granaries and workshops may in these places pre-

dominate over spores coming in with the ordinary outdoor air: such local modification of the spore load may be significant from the point of view of allergy.

Dr. Elizabeth Hamilton (Wright-Fleming Institute) described her current research with the Hirst automatic volumetric spore trap, in which airborne particles are impacted on to the sticky surface of a slowly moving microscope slide. The number of spores counted under the microscope on a traverse of known area can be converted into an estimated number per cubic metre of air, and it is possible also to tell, to within an hour, the time of day when any particle was deposited.

The 'spore-season' in London stretches from mid-May to November. Individual spore types have their particular seasonal incidence and there is within the season a day-to-day fluctuation in the counts, depending mainly on meteorological factors: there are 'associations' of spores which are predominant in dry weather and others which are predominant in wet weather.

Besides the annual and seasonal variations many airborne spores also have a distinct pattern of diurnal periodicity. This is dependent on the individual spore-type and also on the occurrence of those conditions of humidity, temperature and local air turbulence required for the liberation and dispersion of the spores. It is therefore apparent that if spore trapping is not continuous, the time of day when samples are taken will bias the findings.

This information on the season, the abundance, the time of day and the type of weather favouring different spores is all likely to aid the clinician in his diagnosis of spore allergy.

A note of the daily count is given to the Allergy Clinics at St. Mary's Hospital and data sheets summarizing the counts are sent each week to doctors who are interested in allergy.

Mr. R. Harvey (University College, Cardiff) described his investigations into the ecology of the genus *Cladosporium*, at least six species of which are in the aerospora, their proportions ranging at Cardiff from 0.2 to 45 per cent of the total. Under identical conditions growth-rates of individual species vary significantly, and in each species the process of spore production is much more sensitive to adverse environmental conditions than is vegetative development. Conidiophore development at humidities less than 65 per cent is often abnormal, and few spores are produced. Temperatures above or below the optimum range of 15–20°C. restrict sporulation, and at extremes above 27°C. or below 10°C. lead to abnormal conidiophore development. The presence of water droplets in the air markedly accelerates spore liberation.

The 'peak development' of each of the various species is reached at the time of maximum sporulation. Following their release, the further development of the fungus continues to be limited because of the effect of environmental factors (especially humidity) on the spores during their dispersal.

More than 10 per cent of the spores are released in clusters of 30 or more spores, but during dispersion these break up to form smaller clusters and, eventually, single spores. Both large clusters and single spores are essentially dispersal units—each of which effectively produces only one fresh growth on deposition.

Airborne spores are able to colonize a wide variety of ubiquitous organic materials. During spore

germination and subsequent colonization the environment continues to exert a restrictive influence, especially through the competition of other components of the mixed microflora.

The capacity for spore production is so great in each life-cycle that even in the winter months they are always present in the air in appreciable quantities.

The symposium showed that the aerospora has

come to be recognized as a factor, or rather a complex of factors, comparable with those of weather, in the human environment. Observation on these factors is becoming increasingly detailed and precise: it is vitally important to the study of allergy.

POLYMER CHEMISTRY

HIGH polymers were the predominant theme of the proceedings of Section B (Chemistry) of the British Association's meeting in Cardiff. Addresses were given on the technical and commercial developments of new products and their applications, the topics selected being polythene, epoxide resins and silicones. A full session was devoted to a discussion of current work on polymer chemistry, and although it was possible to cover only a small part of their enormous and expanding subject, the four papers presented gave a fair perspective of some of the important problems now engaging polymer chemists.

The recent discovery and commercial development of stereospecific polymers was the obvious starting point, and in the opening address Dr. P. R. Thomas referred to the significant discoveries of Ziegler on the synthesis of linear highly crystalline polythene, and of Natta on the polymerization of propylene and other α -olefins to high molecular weight crystalline products. He then described the investigations carried out by the British Nylon Spinners on the synthesis of stereoregular addition polymers containing amide groups, and in particular the N,N-disubstituted acrylamides:

Using hexane or toluene solutions of lithium ethyl as catalyst, highly crystalline polymers were formed in contrast to free-radical or electron-transfer initiators, such as peroxides or sodium naphthalene, which gave polymers of low tacticity. Significant differences between the physical properties, infra-red absorption spectra and rate of hydrolysis of the isotactic and atactic forms were reported.

When polyethylene is irradiated *in vacuo* with X-rays the main effects observed are the production of hydrogen, cross-linking of the polymer and the formation of unsaturation at points along the chain. The cross-linking results from the union of free-radical centres formed on different chains. Not all the radical centres produced in the irradiation process are used in this way. Some are trapped and are potential centres for further reactions. Dr. T. T. Jones described their use in the grafting of polystyrene chains on to the polyethylene backbone. He showed that the rigidity of the swollen gel, in which polymerization takes place, greatly influenced the grafting reaction. Kinetic measurements indicated that, due to the immobilization of free radicals, the termination coefficient of the styrene polymerization reaction was considerably reduced compared with reaction in free styrene. The observed changes in the dynamic mechanical damping properties of the grafted structure were attributed to the interference of the graft polymer and the intimately mixed polystyrene in the crystallization of the polyethylene.

In the third paper, Mr. J. L. B. Benton reviewed the modern aspects of polymer structure and its relation to properties. He discussed the factors which determine the configuration taken up by the long-chain molecules in the crystalline regions of a high polymer, and showed how these depend on forces within the molecule—which determine the minimum energy configuration of the isolated molecule—and the interaction between molecular chains. Since the configuration taken up is the one of lowest energy, the plane all-*trans* plane zig-zag corresponded to the minimum energy configuration in polyethylene. In polytetra-fluoro-ethylene, the van der Waals's diameter of 2.7 Å (cf. hydrogen 2.2 Å.) caused an overcrowding in the all-*trans* configuration, and this was relieved by twisting each successive carbon-carbon bond 20° away from the precise *trans* form and opening up the tetrahedral bond-angle to 110°. This puts the fluorine atoms 2.8 Å. apart and leads to a spiral chain with thirteen CF₂ groups for each repeated distance. For the same reason he showed that isotactic vinyl polymers (CH₃-CH(R))_n with the *R* groups in corresponding positions—either all left-hand or all right-hand—formed a helical structure. In syndiotactic polyvinyl chloride no overcrowding occurs and the polymer assumes the all-*trans* form.

The crystalline melting point of a polymer is closely related to the flexibility of the chain—the more flexible the chain the lower the melting point, or the higher the potential energy barrier for rotation the higher the melting point. Dr. Benton showed that the same properties have a determining influence on the mechanical properties of the polymer. The transition in an amorphous polymer does not involve bodily movement of whole molecules past each other, but only deformation of chain segments and these are determined by bond rotations. Rubbery properties will thus disappear in some critical temperature range where the thermal energy available to the bonds becomes so low that the co-operative rate of passage of the rotational barriers is reduced to negligible dimensions. This explains the high increase in modulus in the region of the glass temperature.

In the final paper, Prof. A. G. Evans surveyed his recent work on the ionic polymerization of 1:1-diphenyl ethylene. This monomer polymerizes only to the linear dimer 1,1,3,3-tetra phenyl but-1-ene because of the presence of the bulky phenyl groups. The reaction was initiated by cationic catalysts of the Friedel-Crafts type, and reproducible kinetic data were obtained only by working under conditions of extreme purification. No dimerization occurred with stannic chloride as catalyst unless water or hydrogen chloride was present as co-catalyst. There was no optimum ratio stannic chloride: hydrogen chloride, but with water a maximum rate occurred at the ratio 1 stannic chloride: 2 water. Similarly, titanium

chloride requires hydrogen chloride as co-catalyst and this and the above reaction were interpreted in terms of the rate-controlling reaction:

where M is a monomer, D is a dimer and $HM^+(SnCl_5^-)$ is a complex formed in the initiating step.

Prof. Evans said that although lithium butyl formed a complex with the monomer in benzene solution, no dimerization occurred, and this he ascribed to steric influences. In the presence of $TiCl_4 + HCl$ the lithium butyl was, however, a powerful dimerization catalyst. The reaction was heterogeneous and occurred under conditions in which $TiCl_4 + HCl$ alone did not induce reaction. C. E. H. BAWN

CARBON-14 MEASUREMENTS OF KNOWN AGE SAMPLES

By ELIZABETH K. RALPH and ROBERT STUCKENRATH, JUN.

Department of Physics, University of Pennsylvania, Philadelphia, 4

THE reliability of the carbon-14 method of dating was admirably demonstrated initially by W. F. Libby¹ with a series of measurements of samples of known age. These afforded confirmation of the basic assumptions of the method with an accuracy of approximately 10 per cent. Now, eleven years later, greater precision can be achieved with the improved techniques, and measurements of samples of known age are being conducted by several laboratories. These measurements are important because, with counting accuracies of the order of 1 per cent, the basic factors involved in carbon-14 dating must also be tested with equal precision. The basic factors are subject to the following questions: (1) Has the cosmic ray intensity been constant as assumed? (2) Has the equilibrium condition between atmospheric $^{14}CO_2$ and the reservoirs, primarily the oceans, been stable? (3) Is the distribution of atmospheric $^{14}CO_2$ uniform throughout the world? (4) Is the accepted half-life value (5568 ± 30 years) correct? (5) Are the isotopic ratios of the atmospheric carbon unaltered in the process of carbon intake by plants?

These questions cannot be answered individually by measurements of single or small groups of samples of known age; but, when a sufficient number have been dated, the specific answers will become apparent. In the meantime, the contributions of the various laboratories furnish information about the over-all accuracy of the method.

Samples of known age which have been measured in the laboratory at the University of Pennsylvania from 1958 until May 1960 are described here and the carbon-14 determinations are illustrated in Fig. 1 and listed in Table 1. In Fig. 1 the known ages are plotted versus the percentage deviations of carbon-14 counting-rates. These deviations are the percentage departures of each sample (after correction of the counting-rate for the age of the sample) from the average counting-rate value of 39 measurements of oak samples ranging in age from 110 to 203 years before present². A statistical analysis of the data from these oak measurements (see Satterthwaite and Ralph³) demonstrates that within this small range of years, the carbon-14 oak values did not differ significantly from those determined by tree-ring counts of the samples, and that the efficiency of the counter remained stable during the period in which these measurements were made.

Moreover, the average counting-rate value, corrected to 'zero age', is 95 per cent of the value of the oxalic acid standard (National Bureau of Standards

No. 4990). This percentage value agrees with that determined by other laboratories, and with the value decided on at the Groningen Radiocarbon Conference⁴ for interlaboratory standardization. With this basis of calibration, the measurements of samples of known age may be compared with those of other laboratories using the oxalic acid standard. The oak measurements demonstrate, in addition, that this 95 per cent value is in agreement, at least within 1 per cent in counting-rate, with true ages in the time span of A.D. 1849 to A.D. 1756 (the range covered by the oak samples). It is, therefore, the best available basis for calibration for use in carbon-14 dating until the complete time span of known ages has been measured.

In Fig. 1 there appear to be three possible deviations from the average oak value. The deviations occur at 272 (A.D. 1687), 3256 (1297 B.C.), and at 3884 (1925 B.C.) years before present. The first of these, at approximately A.D. 1700, is confirmed by known age measurements of several laboratories⁵⁻⁷. The second deviation (1297 B.C.) may be indicative of a similar fluctuation in that era, or in combination with $P-11$, of an upward trend. Carbon-14 measurements of tree-ring dated *Sequoia* sections by Hans E. Suess⁸ lend support to the latter. The third occurs close to the 2000-4000 B.C. time-interval, where other nonconformities between carbon-14 dates and archaeologically estimated chronologies, notably Egyptian, have been found. These older samples have not

Table 1. LIST OF PERCENTAGE DEVIATIONS OF SAMPLES OF KNOWN AGE FROM OAK STANDARDS

Sample No.	Known age		Percentage deviation from oak standards
	Years A.D. or B.C.	Years B.P.*	
P-263 (oxalic acid standard)			+ 4.99 ± 1.06
P-259	A.D. 1779 ± 5	180 ± 5	+ 0.591 ± 0.551
P-198	A.D. 1773 ± 15	186 ± 15	+ 0.040 ± 0.940
P-226	A.D. 1703 ± 3	256 ± 3	+ 1.039 ± 0.457
P-167	A.D. 1686 ± 16	273 ± 16	+ 2.654 ± 0.564
P-274	A.D. 907 ± 10	1052 ± 10	- 0.134 ± 1.216
P-283	A.D. 753 ± 28	1206 ± 28	- 0.591 ± 0.516
Tikal IV	A.D. 746 ± 5	1213 ± 5	- 0.00 ± 0.168
Tikal I	A.D. 704 ± 9	1255 ± 9	- 0.240 ± 0.215
P-268	A.D. 617 ± 7	1342 ± 7	+ 1.139 ± 0.588
P-272	A.D. 575 ± 10	1384 ± 10	- 0.501 ± 0.408
P-30	525 ± 25 B.C.	2434 ± 25	+ 0.688 ± 0.380
P-222	550 ± 25 B.C.	2509 ± 25	- 0.003 ± 0.445
P-184, P-275	714 ± 9 B.C.	2673 ± 9	+ 1.058 ± 0.842
P-227	1297 ± 7 B.C.	3256 ± 7	+ 2.234 ± 0.457
P-11	1925 ± 75 B.C.	3884 ± 75	+ 2.340 ± 0.246

Average counting-rate of 39 oak measurements = 32.143 ± 0.033 c./m.
* B.P., before present.

Fig. 1. Percentage deviations of samples of known age from oak standards. The 'zero age' counting-rate of 39 oak measurements is represented by the horizontal line through 0 per cent. Standard statistical deviations (one sigma) of the average of the carbon-14 known age determinations for each sample are represented by vertical lines drawn through the midpoints of the known age ranges. For tree-ring dated samples, the midpoints of the known age ranges are assumed to be the average ages of the portions selected for carbon-14 dating. The uncertainties in known ages of the archaeologically dated samples are represented by parallelograms to allow for the possibility that the true age of the sample may lie at either extremity of the given range, thus presenting a greater uncertainty in the known date than if the true date were at the midpoint of the range.

been included in this summary because of the greater uncertainties in the archaeological dating.

If we accept these three fluctuations as significant, the nonconformities in terms of years are as follows:

- P-167 (A.D. 1687) 211 ± 45 years too young
- P-227 (1297 B.C.) 176 ± 53 years too young
- P-11 (1925 B.C.) 186 ± 31 years too young.

It is obvious that these few measurements do not cover completely the time-interval of the past 4,000 years, nor do they answer the specific questions. However, they do indicate that the maximum error in carbon-14 dates due to methodological uncertainties could be of the order of approximately 200 years. In some time-intervals, A.D. 1849–1756, A.D. 900–600, and 500–700 B.C., this maximum error is very much smaller, and perhaps negligible (see Fig. 1). Further conclusions must await the completion of measurements covering the whole known age time span and more regions of the world.

Descriptions of Known Age Samples

A. Dendrochronologically Dated Samples

Oak Samples. *Quercus* sp., probably *alba*. Laboratory standard samples. Thirty-nine measurements of nine different oak samples from Round Top Hill (40° 20' 30" N., 74° 50' 0" W.), Mercer County, New Jersey, U.S.A., elevation 400 ft., which range in age from 110 to 203 years before present. Average age of the nine samples is A.D. 1800.

P-259. *Pseudotsuga taxifolia*. From 'Hitchcock Tree' from Santa Catalina Mountains (32° 25' N., 110° 40' W.), 25 miles north of Tucson, Arizona, U.S.A., elevation 6,500 ft., blown down in 1951. Rings marked A.D. 1774–1784 processed. Expected

date: A.D. 1779 (180 before present). Two counting runs.

P-168. *Pseudotsuga taxifolia*. From Mesa Verde (37° 12' N., 108° 30' W.), Colorado, U.S.A., elevation 6,900 ft., cut in May 1950. Laboratory of Tree-Ring Research No. MVR 3041-6D. Rings marked A.D. 1758–1788 processed. Expected date: A.D. 1773 (186 before present). One counting run.

P-226. *Pseudotsuga taxifolia*. From same section as P-259. Rings marked A.D. 1700–1706 processed. Expected date: A.D. 1703 (256 before present). Three counting runs.

P-167. *Pseudotsuga taxifolia*. From same section as P-168. Rings marked A.D. 1676–1702 processed. Expected date: A.D. 1686 (273 before present). One counting run.

P-274. Pine. From Chetro Ketl, Chaco Canyon (36° 05' N., 107° 55' W.), New Mexico, U.S.A. Laboratory of Tree-Ring Research No. OK-852. The pith year (start of growth) of this tree is A.D. 883. Rings marked A.D. 897–916 processed. Expected date: A.D. 907 (1052 before present). Two counting runs.

P-283. *Pseudotsuga taxifolia*. From Nine Mile Canyon (39° 48' N., 110° 20' W.), Utah, U.S.A., elevation 6,500 ft. Collected by John Gillin in 1930 (University of Utah, Museum of Anthropology No. 21754; 13–3)¹⁰. The pith year of this tree is A.D. 725. Rings marked A.D. 725–781 processed. Expected date: A.D. 753 (1206 before present). One counting run.

P-268. *Pseudotsuga taxifolia*. From Broken Flute Cave (36° 45' N., 108° 50' W.), 40 miles north of Chinle, Arizona. Sample from Room 6, north-east post, Laboratory of Tree-Ring Research No. MLK-127. Rings marked A.D. 610–624 processed. Expected

date: A.D. 617 (1342 before present). Two counting runs.

P-272. *Pseudotsuga taxifolia*. From same section as P-268. Rings marked A.D. 570-580 processed. Expected date: A.D. 575 (1384 before present). Three counting runs.

The dendrochronological analyses of samples P-259, P-226, P-274, P-283, P-268, and P-272 were made by the Laboratory of Tree-Ring Research, University of Arizona, Tucson, Arizona, and those of samples P-168 and P-167, by J. L. Giddings, Brown University, Providence, R.I. Sample P-283 was obtained from the University of Utah, Salt Lake City, Utah; the others, from the Laboratory of Tree-Ring Research. We wish to express our appreciation to T. L. Smiley (University of Arizona), to J. D. Jennings (University of Utah), and to J. L. Giddings (Brown University) for these important contributions to the known age dating project.

B. Archaeologically Dated Samples

Samples obtained from the University Museum of Philadelphia.

Tikal IV and Tikal I. *Achras zapota*. Samples from vault and lintel beams from Temple IV (P-235, P-236, P-237, P-238, P-242, P-243, P-244, P-245, P-248, and P-249) and Temple I (P-230, P-232, P-234, P-247, and P-251), Tikal (17° 13' 18" N., 89° 38' 30" W.), Peten, Guatemala. For Temple IV, thirty-three counting runs of ten different beams and for Temple I, seventeen runs of six different beams were made. According to the "11-16" Maya-Christian correlation, the dates of the Temple IV beams are within the range of A.D. 741-751 (1218-1208 before present) and those of Temple I, A.D. 695-712 (1264-1247 before present). Reasons for acceptance of this correlation and details of samples selected are given by Satterthwaite and Ralph³.

P-30, P-222, P-134 and P-275. Gordion Samples. Gordion (39° 45' N., 31° 55' E.), Turkey is the capital of a Phrygian Kingdom which fell before an invasion of Cimmerian barbarians early in the seventh century B.C. The town (the City Mound) was rebuilt in the time of the Persian Empire and continued to be occupied to about the third century B.C., but most of the numerous tomb mounds were undisturbed until excavations were begun in 1950 by the University Museum of Philadelphia under the direction of R. S. Young.

P-30. Tumulus F, Gordion. Charcoal from an undisturbed cremation-burial. Among the finds was jewellery of the Persian period (post-546 B.C. at Gordion) parallel to that from Tumulus A. Tumulus A was a similar cremation dated by the presence of a terracotta 'kore-unguentarium' with the same front- and back-moulds as those used in Samos in strata dated to the tyrant Polycrates (532-522 B.C.)¹¹. Allowance of a short period for travel to Gordion, and for its worn condition, makes 550-500 B.C. (2509-2459 before present) a reasonable date for the Tumulus A cremation, and, therefore, for Tumulus F. Three counting runs.

P-222. Tumulus H, Gordion. Charcoal from Tumulus H cemetery, Burial A-161, an undisturbed grave of the Lydian period which contained a 'lydion' or ointment-jar painted in the 'marbled' technique. Such lydions have been found associated with the burnt fortification on the 'smaller mound' (KH) at Gordion. Estimated date: 575-525 B.C. (2534-2484 before present). Two counting runs.

P-134 and P-275. Tumulus MM, Gordion. The largest of these mounds (Tumulus MM) contained the 'Gordius' tomb. Young¹² has determined the date of completion of this tomb by parallels with Assyrian objects from the time of Sargon II, who reigned from 722 until 705 B.C. (2681-2664 before present). Samples P-134 (reported previously¹³) and P-275 were found in this tomb and are probably contemporaneous with its completion. P-134 consisted of fragments of organic matter, possibly food, from bowl No. 148, and P-275, of maple (*Acer pseudoplatinus*), part of a table-top, which is believed to have been made for the entombment. There was no necessity for re-use of wood, as the rolling hills on the plateau around Gordion are known to have been forested, on evidence of abundant deer bones found in habitation-levels. These two samples (P-134 and P-275) exhibited no significant differences in carbon-14 counting rates. One counting run of P-134 and three of P-275.

P-227. Seti I Beam. Wooden beam from Egypt with a cartouche containing the name of Seti I who reigned from 1303 until 1290 B.C.¹⁴ (3262-3249 before present). The reign of Seti I has been firmly dated by its relationship to the recorded Sothic cycles. The collection date and original location of this sample in Egypt are not known. The beam is small, approximately 9 × 6 cm. in cross-section. The tree-ring patterns indicate that it was part of a small tree or branch. In other words, the portion used for dating was probably representative of the date of the cutting of the tree and of inscribing the cartouche unless it was an older re-used beam. Two counting runs.

P-11. Aha-nakht Sarcophagus. Wood, probably cedar, from the outer sarcophagus of Aha-nakht, El Bersheh (27° 45' N., 30° 45' E.), Egypt. Found in a tomb which was covered with earth. Aha-nakht lived sometime between 2000 and 1850 B.C. (3959 and 3809 before present), based on the early Kings' lists and archaeological evidence¹⁵. As can be seen in Fig. 1, this sample is not so firmly dated as the others in this list. In addition, there may be a post-sample-growth error (not shown in Fig. 1), that is, the sample dated may be from the inner rings and, therefore, possibly 100 years older than the time of death of the tree. The portion for dating was taken from a beam approximately 45 cm. wide which had been squared and reduced in thickness to approximately 10 cm. Eight counting runs. (Preliminary carbon-14 dates for both P-227 and P-11 were reported previously¹³.)

We wish to acknowledge with gratitude the financial support of the National Science Foundation for these measurements.

OBITUARIES

Prof. N. E. Svedelius, For.Mem.R.S.

PROF. NILS EVERHARD SVEDELIUS, the eminent Swedish botanist, died at Uppsala on August 2. He was born at Stockholm on August 5, 1873, of an old family noted for its scholarship and public service, which took its name from the small town of Sveden, in Dalecarlia. Going to the University of Uppsala in 1895, he was later elected curator of the Stockholm nation. This student office gave him an early acquaintance with the business side of university affairs and led to his abiding interest in administration in which he played a prominent part at Uppsala.

Uppsala has always played a very prominent part in cryptogamic botany, for a long line of eminent botanists have made the different groups their special study. Svedelius, under the guidance of F. R. Kjellmann, who was noted for his researches on Arctic algae, took up the study of those of the Baltic, which provided the subject of his doctorate thesis in 1901. After studying at Munich that year, he journeyed to Ceylon, the East Indies and Java, 1902-3, where he gained a knowledge of tropical algae which ever afterwards stood him in good stead; a paper on the algae of the coral reefs of Ceylon, 1906, was one result of these travels, but their influence is seen in his discussion of the discontinuous geographical distribution of some tropical and subtropical marine algae, 1924. He was a prolific writer on algology, treating practically every aspect of this wide field, but his most important contributions were on the anatomical structure and development, and on reduction divisions and alternation of generations in the Florideae. It may be said that Svedelius and his pupil J. H. Kylin, later of Lund, initiated the study of algal cytology at Uppsala.

In 1908, he found that, in the tetrasporangium of *Martensia*, the tetrad is formed by only one of the numerous cell nuclei. Working with *Delesseria sanguinea* in 1912-14 he confirmed Yamanouchi's discovery of alternation of generations with changes of nuclear phase in the red algae.

In 1915 he discovered that in *Scianata furcellata*, which lacks tetraspores, meiosis sets in immediately after the fertilization of the female nucleus which had invaded an auxiliary cell; one of the four nuclei gives rise to the gonimoblast which has haploid nuclei. Then, in 1933, he showed that meiosis begins immediately after fertilization in *Asparagopsis* and *Bonnemaïsonia*. In monospore cultures, 1937, he proved that in *Lomentaria rosea*, where there are no sexual individuals, tetraspores are formed without meiosis, unlike *L. clavellata*, which is typically diplobiontic, having separate tetrasporous and sexual individuals. In 1942 he found that *Galaxaura*, closely related to *Scianata*, has separate tetrasporous individuals. He finally reached the conclusion, therefore, that the sole criterion of a haplobiontic or diplobiontic development can no longer be regarded as of any great systematic importance.

Svedelius was soon regarded as among the foremost algological systematists; indeed, so early as 1911 he wrote the section on Bangiales in Engler and Prantl's "Pflanzenfamilien".

It would probably be true to say that Svedelius used his extraordinarily wide knowledge of algology

to note problems which needed to be solved if theories based on insufficient facts were not to hold continued sway. By selecting these for the most part, though in no wise neglecting other opportunities which came to hand, he deservedly gained his great reputation.

In 1914 he succeeded H. O. Juel as professor of botany at Uppsala, and praefector of the University Garden. Juel had written a full account of Burser's herbarium and Svedelius saw it through the press. Burser, who died in 1639, left a *hortus siccus* of twenty-five volumes, the result of extensive continental journeys. This, one of the treasures of Uppsala Museum, had many vicissitudes before, surprisingly, reaching Uppsala—and then suffered the loss of two volumes in the great fire of 1702. It contains many specimens of C. Bauhin which enabled Linnaeus to recognize his types. It is of fundamental importance in botanical nomenclature which, however, does not do away with its intrinsic historical value.

Svedelius was an authority on the lives and works of his great predecessors and, not unexpectedly, of Linnaeus. The old University Botanic Garden, which Linnaeus had reorganized and made famous, was left to become scientifically derelict after Gustav III had presented the gardens of the Royal Palace to the University on the urgent representation to him by C. P. Thunberg that the old garden was in a marshy district and otherwise unsuitable. Svedelius was one of the foremost of those who forced through a scheme in the early '20's for rearranging the Garden as it was in Linnaeus's time and to ensure its future care.

Like most Swedish botanists, Svedelius did a good deal to popularize the subject in articles, and also wrote a popular book.

Prof. Svedelius represented Sweden at many botanical congresses and was also personally well known from his visits to foreign institutions. His quiet demeanour, with apt comments when such were in place, together with his evident enjoyment of the humorous gained him general affection.

He held many foreign distinctions. In Britain he was foreign member of the Linnean Society (1917), and the Royal Society (1944), and honorary member of the Botanical Society of Edinburgh (1938).

JOHN RAMSBOTTOM

Sir Arthur Fleming, C.B.E.

THE death of Sir Arthur Fleming on September 14 will have saddened all who are concerned with the improvement of our national facilities for engineering education and training, and most of all those many thousands of men who were privileged to benefit from the schemes of apprenticeship which he pioneered within the Metropolitan-Vickers Electrical Co., Ltd. (now, Associated Electrical Industries (Manchester), Ltd.) more than fifty years ago.

He was born at Newport, Isle of Wight, in 1881, and was educated at the Portland House Academy there and at the Finsbury Technical College in London. After occupying positions with the London Electric Supply Corporation and a firm of instrument makers, he was selected by the British Westinghouse Co., later Metropolitan-Vickers, Manchester, as one of the 'holy forty', to undergo a course of training

with the Westinghouse Electric and Manufacturing Co. at its East Pittsburgh works. On joining the Manchester company, he was engaged as a specialist in electrical insulation and soon became chief designer, and then superintendent and chief engineer, of the Transformer Department.

It was not long before Fleming introduced arrangements for the systematic training and further education of the young men in this Department, and from this beginning grew the Education Department of the Company, of which he became director. He used often to say that the most important raw material of industry was its young people, and he devoted himself to ensuring that his own young people, from the embryo craftsman to the university graduate, were recognized and treated as such. They came not only from schools and universities in Britain, but also from all over the world, for in the sphere of industrial training the names of Fleming and Metro-Vickers became international bywords; and there can scarcely be a country in which there are not several, indeed many, men who hold 'A. P. M.' in honour and who would welcome the opportunity to express their deep gratitude for his efforts on their behalf. His influence and inspiration in this sphere were not, of course, confined to his own Company; they penetrated widely within the electrical industry as a whole, and the benefits they have brought to the progress of this industry have been profound.

All this, however, was only part of his achievement. His far-sighted views on engineering education and training were matched by his realization of the need for research within industry, and especially for research which was not bounded by the problems of existing products. In parallel, therefore, with his establishment of schemes of apprentice training, he began to create a research department within the Company, to which he attracted a succession of men of outstanding ability and who responded to his inspiration by making many notable contributions in pure as well as applied science. A particular example of his remarkable foresight was his forceful contribution to the establishment of radio broadcasting in

Britain. He retired from his directorship of research and education in Manchester in 1952.

Fleming's outside interests and activities were manifold. He was a member of the Council of the University of Manchester, of the Governing Body of the Imperial College of Science and Technology in London, of the Delegacy of the City and Guilds of London Institute, of the Ministry of Education Committee on the Training of Teachers and Youth Leaders, and of the War Cabinet Engineering Advisory Committee; chairman of the Electrical Engineering Committee of the Central Register of the Ministry of Labour, of the Athlone Fellowship Committee of the Board of Trade, and of the Federation of British Industries Overseas Scholarships Committee; and president of both Sections G (Engineering) and L (Education) of the British Association, and of the British Association for Commercial and Industrial Education. He also played an important part in the establishment of the Department of Scientific and Industrial Research and of the Electrical Research Association.

Within all these interests, the Institution of Electrical Engineers occupied a place of special importance; he became a member of its Council in 1932, was elected a vice-president in 1935 and president in 1938; and for his outstanding services to the profession was awarded the Faraday Medal in 1941 and elected to honorary membership of the Institution in 1952.

The Universities of Manchester and Liverpool conferred honorary doctorates upon him; he was made C.B.E. in 1920 for his contribution to submarine detection; and knighted in 1945 for his services to education.

Those who knew him well will remember him with admiration for his exceptional foresight, his unlimited enthusiasm and vitality, his unrestrained willingness to make his knowledge and experience widely available, and his devotion to the needs of the younger generation. Many more who did not know him have cause to be grateful for the benefits that have come from his life of public service. WILLIS JACKSON

NEWS and VIEWS

Chemical Technology at the Imperial College of Science and Technology, London:

J. S. Rowlinson

THE chair of chemical technology in the Imperial College of Science and Technology was held for many years by the late Sir Alfred Egerton, but it was not filled after his retirement in 1952. It has recently been announced that Dr. J. S. Rowlinson, senior lecturer in the Department of Chemistry, University of Manchester, has now been appointed to the chair. Dr. Rowlinson had a distinguished career at Oxford, where he was Millard Scholar at Trinity College. He obtained first class Honours in chemistry in 1948 and the degree of D.Phil. in 1950. Leaving Oxford, he went as a Research Associate to the University of Wisconsin for a year, before going to the University of Manchester, where he was first an I.C.I. Fellow and afterwards lecturer, and more recently senior lecturer. Dr. Rowlinson received a Meldola Medal of the Royal Institute of Chemistry in 1954 and the Marlow Medal of the Faraday Society in 1957. Among his

outside contacts it may be mentioned that he was formerly a member of the Thermodynamics Committee, National Engineering Laboratory, and he is at present a member of the Joint Sub-Committee of the National Physical Laboratory and the National Chemical Laboratory on Fundamental Properties of Pure Materials. He has carried out research on experimental and theoretical aspects of compressed gases, liquids and solutions, and he is the author of a book entitled "Liquids and Liquid Mixtures" published last year. Dr. Rowlinson goes to the Imperial College at a time when it is expanding rapidly.

Physiology at the Royal Free Hospital School of Medicine, London: Prof. C. B. B. Downman

DR. C. B. B. DOWNMAN has been recently appointed to the Sophia Jex-Blake chair of physiology at the Royal Free Hospital School of Medicine, London, in succession to the late Prof. Esther Killick. Dr. Downman was educated at the City of London School and St. Thomas's Hospital Medical School.

In 1937, after preclinical studies, he graduated B.Sc. (Lond.) with first-class honours in physiology and in 1953 he obtained his Ph.D. (Lond.). In 1938, a junior appointment in the Department of Physiology marked the beginning of his research association with the late B. A. McSwiney. In 1941, he was promoted to lecturer and later senior lecturer, until 1954, when he moved to the Royal Free Hospital as reader in physiology. Dr. Downman is well known internationally for his investigations in neurophysiology. His main work lies in the field of visceral afferent reflexology, early papers being concerned with vascular reflexes of skin and with the distribution of afferent fibres of the intestine; the spinal cord and cerebral distribution of splanchnic afferent impulses has been mapped and the properties of the reflexes set up by such impulses has been analysed. More recent work has been concerned with the controls of these arcs in the brain stem. During the Second World War Downman was for a time a member of a team investigating oxygen poisoning at the National Institute for Medical Research under the leadership of Sir Lindor (then Dr. G. L.) Brown. In 1948 he went to Dunedin, New Zealand, for one year, where in collaboration with J. C. Eccles he studied spinal motoneurone physiology. In 1953 he went to the United States and together with C. N. Woolsey studied the interdependence of the subdivisions of the auditory cortex.

The British Biophysical Society

It is proposed to form a new society, to be known as the British Biophysical Society, the object of which will be to provide a common meeting ground for those interested in the functioning and structure of living organisms viewed from a physical point of view and in the application of physical and physico-chemical techniques to biological problems. The first meeting of the new society will be held at King's College, London, during December 19-20. It will consist in part of symposia, with invited speakers, on comparative work on muscular contraction and on the structure of ribonucleic acid, and in part of short contributed papers on the subjects of the symposia or on other subjects. Those interested in joining the Society or in attending (or contributing papers to) the meeting should apply to the honorary treasurer, Dr. P. M. B. Walker, Department of Zoology, West Mains Road, Edinburgh 9. All other correspondence should be addressed to the honorary secretary, Dr. J. C. Kendrew, Peterhouse, Cambridge.

Radioactive Contamination of Materials and Reagents

THE Committee of the International Commission on Radiological Units which is concerned with Standards and Measurement of Radioactivity has appointed a sub-committee to report on problems arising from low-level radioactive contamination of raw materials used in various types of scientific work. Particular attention is being given to: contamination in shielding materials; contamination in the materials used in the construction of detectors and in the mounting of sources; contamination of reagent chemicals used in the separation for analysis of small quantities of radioactive material. The aims of the Sub-Committee are four-fold: to collect general information on the occurrence of contamination, in raw materials, for the information of possible users; to trace the origin of the contamination found in particular materials; to consider whether tests

might be made at certain points in a manufacturing process or in distribution, to ensure that the level of any possible contamination was less than a defined amount; to consider special operations in tracer work or in the preparation and use of standards of radioactivity, where unsuspected radioactive contamination of reagent could lead to significant errors in measurements. The chairman of the Sub-Committee is Dr. N. G. Trott (Institute of Cancer Research), and the members are as follows: Mr. C. O. Peabody (Atomic Energy Research Establishment); Dr. B. Grinberg (Centre d'Etudes Nucléaire de Saclay); Dr. W. W. Meinke (University of Michigan); Dr. R. Brown (Atomic Energy of Canada, Limited, Chalk River). Dr. J. Rundo of the Health Physics Division, Atomic Energy Research Establishment, Harwell, is to act as consultant.

Russian Intelligentsia

THE summer issue of *Daedalus* deals with the condition and prospects of a body of intellectuals known in Russia, pre-Revolutionary and Soviet, as the 'intelligentsia'. In Russia the question of the social function and historic mission of the intellectuals has a particular urgency, first because the early and rapid Westernization of the country produced an extraordinarily large, virile and self-conscious body of intellectuals, and secondly, because there modernization has been carried out with greater intensity and single-mindedness than anywhere else in the world.

What is the 'Russian intelligentsia', or an 'intellectual' or 'intelligent' anywhere? As the passage quoted by Leopold Labedz at the beginning of his essay suggests, these terms can mean all sorts of things to all sorts of people. Some use the term intelligentsia to refer to anyone engaged in non-physical labour, whether he is a lyric poet or a veterinarian (such, for example, is the official Soviet definition); others apply it to a person with a liberal education regardless of the nature of his employment; yet others confine it to persons critically disposed to the existing economic and political order, and ready to sacrifice themselves in order to change it fundamentally in accord with some higher (but secular) ideal. Ultimately, the criterion turns out to be a subjective one, and, to define the term 'intelligentsia' with any degree of accuracy, it would be necessary to have free access to all the groups which could possibly come within the meaning of the term. But this is not possible. The lack of direct access to the Russian intelligentsia of to-day posed difficulties for the writers in *Daedalus*. Rather than seek a comprehensive treatment of the intelligentsia of Russia, it seemed preferable to the authors to concentrate on several crucial aspects of the problem. To begin with, there is the question of the character of the pre-Revolutionary intelligentsia; in particular, its attitude toward civic responsibility. The first of these topics is treated by Martin Malia, the second, from different standpoints, by Leonard Shapiro and Boris Elkin.

"Science, the Endless Frontier"

As part of the observance of its tenth anniversary, the National Science Foundation has re-issued the report, "Science, the Endless Frontier", which Dr. Vannevar Bush, director of the Office of Scientific Research and Development, presented during July 1945 to the President of the United States on a pro-

gramme for post-war scientific research. The report is reprinted as a handsome brochure together with the reports of the four specialist committees—the Medical Advisory Committee, the Committee on Science and the Public Welfare, the Committee on Discovery and Development of Scientific Talent, and the Committee on Publication of Scientific Information. Dr. Bush himself contributes a foreword, and the whole is now provided with an index, which enhances its value to all concerned with the relations between science and government and education. An admirable introduction by Dr. A. T. Waterman, director of the National Science Foundation, summarizes the extent to which the recommendations of the report have been implemented during the past fifteen years and points to some of the problems which still await solution. The reprint is to be welcomed as making readily available to a further generation of those responsible for the ordering of the national effort in scientific research and development in Britain, no less than in the United States, the clear and creative thinking of a distinguished group of experienced and responsible scientists. The report is obtainable from the National Science Foundation, Washington, D.C.

IGY Bulletin

WITH the July issue (Number 37, 1960) the *IGY Bulletin* entered its fourth year of publication. The original aim of the *Bulletin* was primarily to keep participating scientists informed of progress in the United States programme, and to a limited extent, in programmes of other countries, but a large number of students, teachers and other interested persons expressed interest in the work and near the end of its first year of publication the *Bulletin* was made available on a subscription basis. The observational phase of the International Geophysical Year ended on December 31, 1958, but the programmes were continued during 1959 and have been succeeded by world-wide geophysics and space-science programmes. The great body of accumulated data still requires analysis, and the *IGY Bulletin* is being continued in order to complete the record of reports of the International Geophysical Year and the related studies, and of investigations in geophysics and space research as they become available. The *Bulletin* is also re-printed in the *Transactions of the American Geophysical Union*.

The Weizmann Institute of Science

THE annual report for 1958–59 of the Weizmann Institute of Science records a steady increase in support, and the president, Abba Eban, records the intention in 1960 to explore the potentialities of science and technology in the development of new independent States, especially in Asia and Africa (Pp. 108. Rehovoth, Israel: Weizmann Institute of Science, 1960). Of the scientific activities, Prof. A. M. J. Schmidt, chairman of the scientific committee, refers to the expansion of the two-year-old programme of virological research in the Department of Experimental Biology; the exploitation by nuclear physicists of the possibilities offered by the Van de Graaff accelerator for designing experiments along new lines; the growing demands on the electronic computer *Weizac*, to growing international interest in the work of the Biophysics Department; and to the pooling of resources by scientists in the Departments of Biochemistry, Biophysics, Experimental Biology and X-Ray Crystallography for a major collaborative

effort in molecular biology. Much thought has been given to the founding and work of Yeda, a research and development corporation, to foster the commercial exploitation of discoveries made in the Institute's laboratories and to provide stimulus by closer contact with the scientific problems of industry. At the Graduate School in the Natural Sciences there are now seventy-five research students, and eighteen obtained their Ph.D. degree during the year. Besides brief accounts of some of the investigations in progress in the various Departments, the report includes a list of scientific, administrative and technical staff. A list of papers published by members of the scientific staff, 1958–59, has been issued simultaneously with this annual report, but independently, and the library has also issued a definitive edition of "Serial Holdings of the Weizmann Institute of Science, 1959".

An Investigation on Mounting Boards

RECENTLY a report concerning mounting boards has been made by the Fibre Research Institute of the Central Netherlands Organization for Applied Scientific Research at Delft at the request of the Dutch Museums Association. The *Museums Journal* for August, 1960, contains extensive notes from this report. In the past little has been known about the precise properties required in this type of board and it was considered useful to investigate various widely differing boards and so provide a basis for a set of standards. The properties which mounting boards should possess were considered under various headings and include flatness, colour, opacity, resistance to light, polluted air and micro-organisms, durability, strength, bulk and stiffness. The report makes some definite recommendations concerning the factors on which information was sought and the paper quoted gives these in some detail. It is interesting to note, for example, that the board should be free of ground wood and be manufactured from good-quality bleached pulp. For this, unused rags and soft-wood sulphate pulp bleached by the chlorine dioxide process are acceptable.

Bibliography of British Archaeology

THE Council for British Archaeology has produced "A Booklist", slim and paper backed, with 41 pages of book titles and with very occasional explanatory notes as to their contents (Pp. 43. (London: Council for British Archaeology, 10 Bolton Gardens, S.W.5, 1960.) 5s. 6d.). These are divided into sections dealing with: (1) Periods—from the Palaeolithic to the Industrial Revolution; (2) Regional books, covering England, Scotland and Wales; (3) Books for children, and a short section of regional studies of a more elementary nature. The list is intended to help those of all ages who wish to take an intelligent interest in the past of Great Britain whether it be the Stone Ages, the Roman Period, the Gothic architecture, the domestic building or the furniture, clothes, crafts, silver or ceramics which interest them most. It is not stated who is responsible for the selection of titles.

Sinhalese Sports and Pastimes

ATHLETICS have always been popular, but there has often been held an erroneous idea that activities such as wrestling and the like were mainly sports indulged in by peoples living in the more western and northerly parts of Europe. Dr. P. E. P. Deraniyagala, director of the National Museums in Ceylon, has now shown in his fascinating volume "Some

Sinhala Combative, Field and Aquatic Sports and Games", published by the National Museums, that all these activities flourished in Ceylon even many centuries ago (Pp. 51+5 plates. Colombo: Department of National Museums, 1959. Rs. 2.00). The illustrations are delightful, and it is perhaps surprising to see that when wrestling the pulling of one's opponent's long hair was permissible. In one illustration this is being done by the hands, in another by the feet. Besides wrestling there are accounts of combats between men and animals, and also bull-fighting and cocking. Hunting, falconry, horse racing and bull racing are mentioned, as well as a number of field and water games. Those keen on sports generally will be very interested to peruse this revised edition of Dr. Deraniyagala's important work.

Gyromagnetic Ratio of the Proton

In order that all measurements of the intensity of the geomagnetic field, made by investigators and observers throughout the world, might be referred to the same fundamental physical constant, the following recommendations were made by the Association of Geomagnetism and Aeronomy, International Union of Geodesy and Geophysics, at the twelfth general assembly of the Union in Helsinki, Finland, during July 25-August 6: "The International Association of Geomagnetism and Aeronomy, considering the need for a universal agreement regarding the value of the gyromagnetic ratio of the proton for measurements of the geomagnetic field, strongly recommends that, pending the agreement and specification by an appropriate international scientific organization of a final value, all measurements of the geomagnetic field with a proton free-precession magnetometer, using pure water as a proton sample, shall be based on the following value of the gyromagnetic ratio: 2.67513×10^4 radians/gauss sec."

Classification of Mental Disorders

PSYCHIATRISTS disagree about the concepts on which a classification of mental disorders should be based; hence the many classifications, and the frequent description of the same or similar conditions under a confusing variety of names. The effect of this diversity of classifications has been to defeat attempts at comparing psychiatric observations and the results of treatment in different countries, or even in different centres of the same country. In recent years the epidemiological approach to mental disorders has been more and more employed. To be used successfully and on a wide scale such an approach requires a common basic terminology and classification. As a first step towards this, Prof. E. Stengel, of the University of Sheffield, has examined the classifications in current use ("Classification of Mental Disorders", by E. Stengel. Offprint from *Bull. World Health Org.*, 21; 1960. 3s. 6d. 0.60 dollars. Sw. Fr. 2). He shows that some of the difficulties created by present-day lack of knowledge are surmountable by the use of "operational definitions", and outlines the basic principles on which a generally acceptable international classification could be constructed.

Tissue Injury by High-frequency Electric Current

IAN K. BUCKLEY, of the Department of Pathology, University of Melbourne, has employed high-frequency current to produce minute injuries to selected blood vessels within Sandison-Clark rabbit ear-chambers. There are two principal findings, which he outlines in the June edition of the *Australian Journal*

of *Experimental Biology and Medical Science*. First, at the surface of injured endothelial cells, transparent blister-like structures appear which, after increasing in size, separate from the cell as transparent globular bodies, floating freely in the plasma. He concluded that these structures are produced by the damaged endothelial cells. Secondly, the area of vascular damage apparent within 1 hr. of injury is increased five-fold by 24 hr. It is suggested that the initially injured cells may release diffusible chemical factors which secondarily injure the surrounding endothelial cells. Alternatively, or perhaps additionally, this phenomenon may be due to initial latent cell injury which only gradually becomes visible with the passage of time. Further consequences of cellular injury were the very rapid formation of cytoplasmic vacuoles by some cells and the active migration of granular leucocytes to the site of the injury. Leucocyte accumulation under these conditions strongly suggests a chemotactic effect by products of injured cells.

Blast Disease of Oil Palm

IN Central and West African oil palm (*Elaeis guineensis*) growing regions, a severe nursery root disease, occurring at the end of the rainy season and known as 'blast', has caused serious losses and dislocation of field planting schedules during recent years. The diagnosis of the disease has proved to be difficult and troublesome. J. S. Robertson, of the West African Institute for Oil Palm Research, Nigeria, has now attributed the disease to the co-infection of roots by a species of *Pythium* and *Rhizoctonia lamellifera* (*Trans. Brit. Myc. Soc.*, 42, 401; 1959). The leaf and root symptoms of blast disease are described. Isolations from roots in an advanced state of decay yielded *Rhizoctonia lamellifera*, whereas isolations from primary infections yielded a *Pythium* species. Inoculation experiments are reported which demonstrate that typical blast symptoms develop only when a mixed inoculum of *R. lamellifera* and *Pythium* sp. is employed. A laboratory experiment showed that *R. lamellifera* is capable of parasitizing the *Pythium* species.

National Certificates in Biology

IN view of the increasing measure of support for courses leading to the award of endorsed certificates in biology, and of the growing importance of this subject in industry and public services, the Secretary of State for Scotland and the Institute of Biology have agreed that the stage has been reached at which a national scheme in Scotland should be introduced. They have accordingly decided to appoint a joint committee, representative of the Institute and the Scottish Education Department, to receive and approve schemes for Ordinary and Higher National Certificates in biology. This is discussed in a recent issue of the *Journal of the Institute of Biology* (7, No. 3; July 1960). The Joint Committee is preparing instructions supplementary to those already provided for other National Certificates for the guidance of colleges wishing to submit schemes. Copies of these instructions may be obtained on application to the Joint Secretary, Joint Committee for Biology, Room 385, St. Andrew's House, Edinburgh 1.

The Tarlton Rayment Collection of Australian Insects

MR. TARLTON RAYMENT recently donated his collection of Australian bees, wasps, thrips and mites to

the Commonwealth Scientific and Industrial Research Organization. These will be added to the comprehensive collection of the Organization's Division of Entomology and will become part of the Australian National Insect Collection. Mr. Rayment has earned world-wide recognition as an authority in the Hymenoptera, especially the Aphidae, both for his work in classifying the Australian species of the latter, and for his interesting studies on their biology. The collection is regarded as a very important addition to the National Collection as it contains many type specimens and hence will be widely used for reference work.

Harkness Fellowships of the Commonwealth Fund

THIRTY Harkness Fellowships of the Commonwealth Fund are tenable for 1961 in Continental United States and are offered, in separate series, to candidates from the United Kingdom, Australia and New Zealand, and Western Europe. The Fellowships are offered to candidates from the United Kingdom who are British subjects and either are graduates or have experience in government service, the professions, the creative arts, journalism, branches of business or industry, or other comparable careers and vocations, and have the equivalent of a degree in qualifications conferred by professional bodies or an attested level of professional accomplishment. Forms of application, which must be returned before December 1, can be obtained from the Warden, Harkness House, 38 Upper Brook Street, London, W.1, from whom further details can be obtained.

The Association of Consulting Scientists

THE following have been elected honorary officers and members of the Council of the Association of Consulting Scientists for 1960-61: *Chairman*, Dr. J. G. Davis; *Honorary Treasurer*, Dr. G. W. Ferguson; *Honorary Secretary*, Mr. W. H. Stevens; *Members*, Dr. M. Barent, Dr. H. H. Chambers, Dr. J. Grant, Dr. J. H. Oliver, Mr. O. W. Roskill, Mr. F. G. Sarel Whitfield.

Medical Research Council: Tropical Medicine Research Board

THE Medical Research Council recently established a Tropical Medicine Research Board to advise them on the promotion and co-ordination of all research in this field. The membership of the Board includes the following: Sir Harold Himsworth (chairman); Prof. A. C. Frazer (vice-chairman); Brigadier Sir John Boyd; Prof. P. C. C. Garnham; Prof. W. E. Kershaw; Dr. R. Lewthwaite; Prof. G. Macdonald; Prof. B. G. Maegraith; Prof. B. S. Platt; Prof. M. L. Rosenheim; Mr. H. J. Seddon; Prof. E. T. C. Spooner; Prof. A. W. Woodruff; Dr. B. S. Lush (secretary). The Chief Medical Officer and the Head of the Research Department of the Colonial Office have been appointed assessors on the Board, and two assessors have been nominated by the Secretary of State for Commonwealth Relations.

Medical Research Council: New Members

THE Committee of Privy Council for Medical Research has re-appointed the Right Hon. the Earl of Limerick and, in succession to Sir Geoffrey Vickers, have appointed Dr. E. F. Collingwood to membership of the Medical Research Council. Lord Limerick will continue as chairman of the Council and Dr. Colling-

wood will serve as treasurer. Prof. T. Crawford and Prof. W. M. Millar have been appointed members of the Council in succession to Prof. G. Payling Wright and J. D. N. Hill, who are retiring after their normal four-year term of service. All these appointments dated from October 1, 1960.

Announcements

PROF. B. BLEANEY and Dr. James Cook have been appointed members of the Council for Scientific and Industrial Research. Together with a third member yet to be appointed, they succeed Prof. P. M. S. Blackett, Sir Eric Ashby and Mr. H. Douglass, who have retired on completion of their period of service.

DR. J. M. WINTERBOTTOM has been appointed director of the Percy Fitzpatrick Institute of African Ornithology, University of Cape Town, and took up his office there on September 1.

DR. W. S. STILES has been elected president of the Illuminating Engineering Society for 1960-61. Dr. Stiles is a deputy chief scientific officer at the National Physical Laboratory, which he joined in 1925. His work in the past has included problems of vision, photometry, illuminating engineering, and visual response by psychophysical methods; his discovery with Dr. B. H. Crawford of the directional sensitivity of the retina being his best-known contribution. He was elected to fellowship of the Royal Society in 1957 for his work on vision.

THE first major exhibition on atomic energy to be held in Edinburgh opened at the Royal Scottish Museum on October 15. The exhibition, which has been mounted by the Atomic Energy Authority, will continue until October 29; it will provide a comprehensive review of Britain's nuclear power programme and of Scotland's contribution to this major scientific and industrial effort. The exhibition will illustrate the way in which Britain's research and development resources are being deployed to meet the future power needs. These are likely to be well over double the present level, expressed in terms of coal equivalent, by 1975.

THE ninth International Colloquium on Spectroscopy will be held at Lyon during June 5-10, 1961, under the auspices of the 'Groupement pour l'Avancement des Méthodes Spectrographiques'. Further information is available from Groupement pour l'Avancement des Méthodes Spectrographiques L.N.E., 1, rue Gaston-Boissier, Paris 15e.

THE twenty-first International Conference of Pure and Applied Chemistry will be held during August 2-5, 1961, and will be followed by the eighteenth International Congress of Pure and Applied Chemistry during August 6-12. Both meetings will be held in Montreal. Further information is available from the Secretariat, National Research Council, Ottawa, Canada.

A THREE-DAY symposium on Control of the Mind is being organized by the Medical Center of the University of California at San Francisco during January 28-30, 1961. The symposium is being organized with financial aid from the Schering Foundation. Further information can be obtained from the Department of Continuing Education in Medicine, University of California, Medical Center, San Francisco 22.

ORGANIZATION AND FINANCING OF BIOCHEMICAL RESEARCH IN BRITAIN

A JOINT session of the Biochemical Society and Section I (Physiology and Biochemistry) of the British Association was held in the Department of Biochemistry, University College, Newport Road, Cardiff, during the afternoon of September 7, the closing day of the annual meeting of the British Association. The session was organized on behalf of the Biochemical Society by K. S. Dodgson and W. J. Whelan and took the form of a colloquium, with contributions by nine principal speakers, on "The Organization and Financing of Research in Biochemistry and Allied Sciences in Great Britain". The meeting was under the chairmanship of Prof. John Pryde and was attended by about a hundred members of the two organizations.

Prof. A. Haddow, director of the Chester Beatty Research Institute, introduced the subject in a general way, pointing out the unfavourable and widening gap between the research efforts of Britain and those of the United States and the Soviet Union, and then turned more specifically to the organization and financing of the British Empire Cancer Campaign. Dr. F. J. C. Herrald, Sir William Slater and Mr. C. Jolliffe described the activities of the Medical Research Council, Agricultural Research Council and Department of Scientific and Industrial Research respectively, while Dr. G. F. Marrian gave an interesting account of the work of the Imperial Cancer Research Fund and of the new research laboratories now under construction in Lincoln's Inn Fields. Prof. F. C. Happold had collated information from professors of biochemistry in Britain, and spoke of the problems, particularly financial, which are facing university biochemists. The activities of industry (particularly the pharmaceutical industry) in the field of biochemistry were outlined by Dr. F. A. Robinson, of Allen and Hanburys, Ltd., while Dr. J. B. Bateman, deputy scientific attaché to the American Embassy, spoke of the contributions of the United States in providing support for biochemistry and related sciences in Britain. Finally, Prof. A. Neuberger summarized the proceedings and pointed to the steps which need to be taken if Britain is to maintain its high position in the field of biochemical research.

Contacts with numerous members of the audience prior to the meeting suggested that the real problems surrounding biochemical research are financial rather than organizational. In this connexion, a glance at the list of participants might have indicated that the speakers could be separated into two categories, namely, those distributing financial aid and those receiving it. The possibility of the meeting dividing sharply into two factions thus existed but, happily, did not materialize. Indeed, there was a general appreciation of the considerable assistance which various bodies have provided for all fields of biological research with the funds at their disposal, and of the sympathetic way in which applications are handled by them. In turn, it was clear that officials of these bodies are well aware of the problems facing research biochemists, particularly those working within the universities.

Several points of importance emerged during the course of the meeting. In the first place, it was clear from figures presented by Prof. Haddow that, in spite of the difficulty of translating the currency figures of various countries into absolute and meaningful terms, there is a widening gap between the amount of financial aid available for research in biological and medical sciences in Britain compared with that available in the United States or the U.S.S.R. Prof. Haddow reminded his audience of the blunt words of Sir Harry Melville earlier this year: "Whether we like it or not, the age of string and sealing wax has come to an end, and the pursuit of scientific knowledge is now a rather expensive and complex affair in which substantial resources in men, material and facilities are needed". Apart from the discrepancy in financial effort, there is also some degree of contrast between the principles applied in financing research in the United States and those applied in Britain. In the United States, money is being provided for medical research, including biochemistry, on a scale which we in Britain would regard as lavish. There is a tendency to assume that expansion on this scale must inevitably result in a dilution of scientific standards and attainments. In fact, there is increasing evidence to show that the great and rapid expansion resulting from the American system has not diluted scientific standards, but rather has elicited talent which might otherwise not have become manifest.

In contrast, financial assistance for research in Britain is not so readily available, and the case must be forcefully and compellingly presented to the appropriate organization in order to obtain the necessary financial support. In considering applications for financial assistance, the Medical Research Council, the Agricultural Research Council and the Department of Scientific and Industrial Research attach great (perhaps too much) significance to the ability and reputation of the grant-seeker and the 'timeliness and promise' of the proposed research work. However, what might appear to be of timeliness and promise at the moment may not appear so twelve months hence. Other work which appears to have little import or significance at the time (and which may therefore remain unsupported) may well provide the vital answer to a problem which develops in five or ten years time. In order to cope with this problem, so far as university departments of biochemistry and allied sciences are concerned, Prof. Happold pleaded that the universities themselves should be given more adequate sums for distribution among their departments. The distribution of such sums should be under the control of an internal university committee composed of those in a position to judge the needs. Prof. Happold pointed out that it is the universities (the source of a large proportion of the research in biochemistry and other biological sciences) which are particularly affected by inadequate financial support. Indeed, the head of a department had informed him that, "If the apparatus which has been bought with gifts from the Royal Society, the Rockefeller Foundation or the M.R.C. were taken

away from this department, I can safely say that every single major line of research at present being pursued here would stop at once". Support for Prof. Hapgood's plea came from the body of the meeting during discussion periods, and it was clear that a strong feeling existed that university departments urgently need greater financial support from within the universities themselves.

Two further inter-related points which emerged from the colloquium were, first, that biochemistry is still primarily a research subject, and secondly, that there is already a shortage of trained biochemists in Britain. In relation to the first point, Dr. Robinson produced some interesting figures which suggested that comparatively few biochemists are employed in industry and that, generally speaking, they tend to take subordinate roles. However, Dr. Robinson did stress that his figures related particularly to the pharmaceutical industry, and it seems to the present writers that reference to other industries, for example, the food industry, might provide a more favourable picture. On the second point, Sir William Slater pointed out that it has become increasingly difficult to obtain suitably qualified research biochemists and that the brakes on the progress of the biochemical work of the Agricultural Research Council have not been shortage of funds but shortage of the right men. Further point was given to this statement by Dr. Marrian, who said that the development of the work of the Imperial Cancer Research Fund and the opening of its new Institute will mean that the number of qualified research workers employed by the Fund will increase from the present level of about 30 to between 80 and 100 by 1964-65. Approximately one-third of these will probably be biochemists. At the present rate at which trained biochemists are emerging from the universities, one suspects that Dr. Marrian will experience difficulty in recruitment on this scale.

In his summarizing remarks, Prof. Neuberger struck at the very root of this problem by pointing out that several British universities do not yet have departments of biochemistry, and he appealed to the universities to see that this defect is speedily remedied. In his own University of London, although there are a number of biochemistry departments concerned

with the instruction of medical students, there are only two departments catering for a science degree in the subject, and the combined intake of these departments is limited to about twenty students a year. Prof. Neuberger further stressed the frustration felt by university biochemists of high standing who are unable to progress to senior status because of the rigidity of establishment. He pleaded for the speedy creation of new chairs of biochemistry and the introduction of personal chairs in this and related subjects. Citing the case of Harvard University, with its five professors within what is probably the best organic chemistry department in the world, Prof. Neuberger said that this is one aspect of the American university system that we should be prepared to adopt.

Bearing in mind the comments of Dr. Robinson regarding the subordinate position of biochemists in industry, Prof. Neuberger suggested that it might be time to do some re-thinking as to the way in which biochemists in Britain are trained. For example, is a training in organic chemistry being given which is sufficient for the needs of industry? Should the universities encourage the biochemist who is perhaps not ideally suited for a research position to think of a teaching post in a grammar or public school? The student population of the schools might then become more aware of the possibilities of biochemistry as a career, and this in turn might stimulate the flow of recruits to the profession.

During the two periods which were allocated to discussion, many members of the audience took the opportunity to ask questions and to state their own views. From later discussions which took place during an informal supper, it was clear that the colloquium had been a most successful venture and, in particular, many people expressed their appreciation of the co-operation of the various research councils and similar organizations in providing such interesting accounts of their activities. The meeting has raised a number of points which appear to merit further investigation and a number of problems which, it seems to the present writers, should now be actively pursued by the Biochemical Society for the good of British biochemistry and, indeed, for science as a whole.

J. PRYDE

RESEARCH FOR INDUSTRY

"RESEARCH for Industry 1959"* follows the general pattern of the previous year's report. The report of the Industrial Grants Committee, which this year discusses the coverage of the Government scheme and co-operation in three specific areas—creep research, fatigue of metals and shipbuilding research—is accompanied by a review of the achievements of a dozen of the Associations, the terms of grant of which have been reviewed during the year; and, under "The Research Associations To-day", there is the now customary list of Associations, giving their officers, income, publications and a brief indication of the present scope of the work of each Association. To the total income of the Associations

in 1959 of £7.3 million, the Department of Scientific and Industrial Research contributed £1.7 million.

In place of the two special chapters in last year's report dealing with the place of the research associations in the evolution of scientific endeavour and the service of co-operative research to the textile industry, there is a chapter by Dr. J. Thomson on instrumentation and automatic control in industry, which surveys briefly recent progress in this field in various industries, particularly under the headings of detecting elements, indicators and recorders, and controllers. The British Scientific Instrument Research Association seeks first to serve the scientific instrument industry and secondly, to bring large users of instruments into contact with manufacturers. Besides current investigations into the structure and control of thin films, of glassy phosphors, particularly

as detectors of high-speed neutrons, and of the parameters of optical receiving systems with particular reference to frequency response measurements, the Association has just completed the development of an ultrasonic flowmeter, under the sponsorship of the National Research Development Corporation. The Industrial Grants Committee stresses its anxiety to foster a free exchange of information in this field between the many research associations concerned.

In regard to coverage, the Industrial Grants Committee notes that the admission of the Water Research Association, which in its new premises at Medmenham, Bucks, will be concerned with rapid methods of water filtration, algal growth in stored waters, and the disposal and reclamation of water-works sludge, brought for the first time the number of organizations in the Government scheme to fifty. Only forty-one of these bodies, however, have the formal and permanent status of a research association; the others, with the title, usually, of research council, committee or organization, being as a rule young concerns in an experimental stage. Stress is laid on the need to increase greatly the scale of research on creep. The new building being erected at the National Engineering Laboratory for completion in 1961 will permit basic researches to be expanded with the view of obtaining a better understanding of the creep process and of those properties relevant to the successful use of engineering materials at high temperatures; in the meantime, a Creep Information Centre has been opened to enable industrial designers to obtain creep data not at present readily available in a co-ordinated form. The Electrical Research Association is also planning an extended programme of tests to provide new information on those ranges of steels and temperatures of particular relevance to modern steam-raising plant and turbines, especially for generating electric power. The National Physical Laboratory will analyse and evaluate the relevant metallurgical data obtained on a range of selected steels, and co-operative creep tests are being made by several steel firms organized through a committee of the British Iron and Steel Research Association.

A committee of nine members, under the chairmanship of Sir Alfred Pugsley, has been set up to consider what research needs to be done into the fatigue of engineering structures made of metal, to survey existing research facilities and to make recommendations to the Department. In regard to shipbuilding research, besides the work of the British Shipbuilding Research Association and Parsons and Marine Engineering Turbine Research and Development Association, which is specially reviewed in the report, much useful work on ship hydrodynamics has been done at the National Physical Laboratory, and it is intended to concentrate in the new laboratory at Feltham all research and commercial tests relating to rough water and all work on steering and manoeuvring problems, and to conduct smooth-water tests at Teddington. The Industrial Grants Committee is encouraging as much flexibility as possible in the programmes of the two research associations, and the report refers to the virtual completion by the British Shipbuilding Research Association of an extensive methodical series of hydrodynamic experiments on models of ocean-going merchant ship forms, the charts compiled from which should provide naval architects with a standard work of reference for estimating the resistance and power required for propulsion of any new form of ship's hull within a

wide range of variables. The Association also operates an establishment for testing full-scale components of ships' structures and is concerned with all types of propelling and auxiliary machinery on ships, other than steam and gas turbines, which are dealt with by the Parsons and Marine Engineering Turbine Research and Development Association. Research and design studies by this Association have led to the production of turbine machinery of advanced design, with a 27.5 per cent reduction in overall fuel consumption and a 53 per cent reduction in the weight of marine turbines and gearing between 1945 and 1958. A special hydraulic transmission has been developed with ahead and astern units, together with a friction clutch for running ahead under steady conditions. Tests on a small steam turbine at temperatures up to 1,150° F. have yielded much valuable information, and an experimental liquid-cooled single-stage gas turbine has been designed which shows promise of giving appreciably better performances than the steam turbine. Full-scale tests of hardened and ground naval gears, and through-hardened merchant-marine gears have permitted designs of higher loading to be applied to the propulsion of merchant ships.

Among recent achievements of the British Cast Iron Research Association noted in this report may be mentioned outstanding progress in work on the causes and elimination of defects in iron castings, its development of a successful external system of dust control for stand grinders in fettling shops, the establishment of much more precise correlations between mechanical properties and structure of cast iron and between melting processes and properties, and the complete definition of the conditions for producing shock-resistant nodular cast iron. The British Steel Castings Research Association's steel-making section has constructed control curves permitting prediction, for any temperature of steel-bath and any initial oxygen content, of the amount of oxygen to be injected after the carbon flame appears in order to give a predetermined reduction in the carbon content of the bath. Other work seeks to provide basic data on the physical properties of cast steel, and the Association is also studying the control of both dust and noise when using portable fettling tools.

The File Research Council has established a maximum forging temperature by studying the metallurgical treatment of high-carbon file steel, and a study of metal flow during tooth-cutting has enabled the relation between tooth shape and chisel angles to be determined. The British Welding Research Association's tests of welded steel plates 3 ft. wide and 1 in. and 3 in. thick have established the relative importance in brittle fracture of weld defects, residual stresses, and quality of steel, and extensive work on the welding metallurgy of aluminium alloys has facilitated the selection of filler alloys. Fatigue tests have confirmed the serviceability of butt-welded pipes provided the root-run is sound and the penetration bead is smooth. The Chalk, Lime and Allied Industries Research Association, now in its fifth year, has been concerned chiefly with possible new uses for lime, the examination of factors affecting the quality of lime, and with the manufacture and use of sand-lime bricks. The Research Council of the British Whiting Federation has clearly indicated the possibility of considerable improvements in whiting manufacture by producing a range of

more uniform and finer-quality powders, and its work on quality control and grading has led to the adoption of a comprehensive system of grading by size characteristics, with limits for chemical impurities.

Basic research by the British Leather Manufacturers' Research Association in the past five years has been concerned with the hide and skin proteins and the isolation and identification of constituents of vegetable tanning materials. In applied research the advantage of sodium chlorite over sodium hyperchlorite as an antiseptic in soaking has been demonstrated, and a water-proofing process developed in which the addition of rubbery polymers to the silicone solution greatly reduces the amount and cost of silicone needed. An intensive study of batch tannages in the laboratory and on the small-works scale enabled the duration of vegetable tanning to be reduced from 6-12 weeks to 14-21 days. The Hosiery and Allied Trades Research Association has given considerable help in the development of new knitting and wet-

processing techniques for tailored synthetic fibre yarns, and suggested a scheme for the continuous processing of nylon hose. The British Launderers' Research Association has established the practicability of medium-temperature washing and cold-water rinsing, and has set up a Special Projects Group to investigate and develop new methods and equipment which should permit laundering on a continuous-flow basis. Psychological tests on apprentices in nineteen firms by the National Institute of Industrial Psychology have yielded a good correlation between performance at the tests and performance at technical colleges, and the tests should give a valuable forecast of probable performance during apprenticeship. Work still in progress includes inquiries into relations between satisfaction and efficiency at work, between management structure and managers' satisfaction and effectiveness in their work, methods of measuring 'personal' values relevant to people's occupations and the development of new tests of colour vision and colour-matching skills.

THE FRANKLIN INSTITUTE

AT the annual meeting of the Franklin Institute held on January 20, the president, Mr. W. L. LePage, gave a summary of the activities of the Institute during 1959, and presented the annual report of the board of managers for 1959*.

The year 1959 marked the one hundred and thirty-fifth anniversary of the founding of the Institute and the twenty-fifth of its fine building on the Parkway, Philadelphia, and the report makes special mention of the remarkable growth of the Institute's activities since its modest beginning in 1824 as an organization for the mutual benefit of a few citizens of Philadelphia. To illustrate the Institute's present wide sphere of influence, the highlights of the activities for 1959 are presented in the annual report in the form of a spiral, the focus of which is taken as at the Institute's headquarters in Philadelphia and the unbroken curves of which reach out through the Delaware Valley, the nation, the world, and the universe beyond our planet. Each of these areas is taken as the title of one of the sections of the report, and the Institute's activities are discussed according to the area in which their contributions to science were the largest.

Five of the Institute's main activities—the Science Museum, the Astronomy Department, the educational radio and television programmes, the science meetings, and the Library—are confined almost entirely to Philadelphia and the Delaware Valley. The number of visitors to the Museum during 1959 was 410,433, of whom approximately 290,000 were school children. Sixteen permanent exhibitions were added during the year, of which the two most spectacular were the full-size *Matador* missile and the smoke tunnel in the Hall of Aviation. The demonstration, "Our Biggest Satellite—the Moon", which was shown in the Astronomy Department during September–October, proved extremely popular since that period coincided with the launchings of the *Lumik II* and *Lumik III*. Other exhibits included a *Vanguard* exhibit and a

model of the 600-ft. radiotelescope which is being erected in Virginia. The radio and television programmes for schools in the area consisted of a weekly series of radio broadcasts covering science subjects and six television broadcasts featuring aspects of work being carried out in the Institute's laboratories. The titles of the twenty-one lectures presented at the Institute's meetings are listed in the report. They include, "The Impact of the International Geophysical Year on Science and Engineering" given by H. Odishaw; "Fundamental Particles" by H. A. Bethe; "The Fuel Cell" by H. A. Liebhafsky; and "The Science of Yesterday, To-day and To-morrow" by W. F. G. Swann. The number of accessions to the Library during the year was 4,281, bringing the total of holdings to 167,135, and the number of journals currently received rose to 1,336, including nineteen Russian journals and fourteen English translations of Russian serial publications.

In recent years the part played by the Institute in the scientific life of the United States of America has grown greatly in importance, mainly because of the work of the Institute's Laboratories and the series of technical symposia and conferences sponsored by the Institute. The symposium on space medicine electronics, held in the spring, and the international symposium on gas-lubricating bearings, held in the autumn, attracted large audiences from afar. The Computing Centre, which completed its third year of operation in 1959 and its first year as a separate activity, drastically reduced its machine-use charges and many more industrial firms availed themselves of its services. Contracts received during 1959 by the Institute's Research and Development Laboratories passed the four million dollar mark for the first time. New equipment included the latest model electron-microscope and Varian instruments used in studies of nuclear and electron-spin resonance. Projects undertaken included the production of an ultra-pure iron bar of 1-in. diameter by zone refining; apparatus to measure speed by detecting the light of an ionized gas at two points along the travel of a

* A summary and full text of the illustrated report appear in the April issue of the *Journal of the Franklin Institute* (288, 315; 1960).

wave; the preparation of a text-book on thermal stresses in nuclear reactors; and several projects related to missiles and satellites, including the design and construction of an advanced type of satellite.

By its Committee of Science and the Arts, its *Journal*, and by the work of the Biochemical Research Foundation, for which the Institute serves as trustee, the Institute is best known throughout the world. The Medal Day ceremonies organized by the Committee were held on October 21, 1959. The seventeen individual recipients included H. A. Bethe, C. H. Townes, and C. M. Zener, and one industrial company. One of the achievements of the Biochemical Research Foundation in its concentrated attack on cancer was the successful isolation of a unique streptomycin-independent strain of *E. coli* which can be used as a screening organism in a search for anti-mutagens. Long-term studies of the effects of nutrition on cancer growth were continued, as well as studies of the metabolic processes of cancer cells. In addition to the *Journal* the Institute now issues *The Institute News* eleven times a year, and although intended primarily for Institute members, this four-page newspaper is also distributed to schools, libraries and others interested in science education.

The cosmic ray group of the Bartol Research Foundation of the Institute participated in the

International Geophysical Co-operation, and constructed a new cosmic ray monitor for installation at McMurdo Naval Air Facility in Antarctica, to complement the one in operation at Thule, Greenland. The detector for heavy nuclei contained in the satellite *Explorer VII* was designed by the Foundation. The Foundation's headquarters are located on the campus of Swarthmore College, and in addition to providing an active programme of scientific colloquia and public lectures, undergraduate students of the College have been encouraged to participate in the Foundation's research programme.

The report concludes by emphasizing that, though the Institute's Laboratories and the Foundation are self-supporting, the accounts indicate that the educational and general activities of the Institute, which must expand to meet the growing need, will soon face a critical financial situation. A total of approximately 204,000 dollars was received in 1959 in gifts, bequests and from other sources, but the net loss for educational and general activities, though reduced from the 1958 figure of 100,000 dollars, was still more than 20,000 dollars, and will rise as the planned expansion gets under way during the next decade. The managers of the Institute appeal to the increased generosity of members and friends of the Institute to provide the necessary additional funds.

THE ATOMIC ENERGY OF CANADA LIMITED

THE need for, and the extent of, a nuclear power programme in Canada is one of the main topics of discussion in the annual report of the Atomic Energy of Canada Limited for the year ended March 31, 1960, which has recently been published*. Although Canada has vast resources of oil, gas, coal and untapped water power, these are not uniformly distributed across the country and already some regions are approaching the point where the conventional power resources will need to be supplemented by nuclear power. The industrial area of southern Ontario is likely to be the first of these regions, and it is fortunate that conditions in this area are favourable to the early introduction of nuclear power, for not only is the generating capacity of the Hydro-Electric Power Commission which serves Ontario capable of absorbing the additional 200 or so megawatts, but also there are present in the province of Ontario extensive uranium deposits and large uranium mines.

After considerable examination of the various alternatives and several years experience in the operation of such reactors, it is still the conviction of Atomic Energy of Canada Limited that the type of reactor which is fuelled by natural uranium and moderated by heavy water offers the best promise for early, low-cost nuclear power in large units. The four nuclear power projects which the authority has in hand are described in detail in the report. The first two, the Nuclear Power Demonstration Station being built at Rolphton some twenty miles west of Chalk River, and the Douglas Point plant, are closely related. The reactor at the Nuclear Power Demonstration Station is moderated and cooled by

heavy water and uses pressure tubes instead of a pressure shell to contain the coolant. The fuel consists of natural uranium dioxide pellets sheathed in 'Zircaloy' tubes, and the tubes are grouped together in bundles. The Station, which is expected to have an output of 20 MW. (electrical) and to go into operation during 1961, is a prototype, and the results of tests carried out at the Station will be used to improve and modify the design of the Douglas Point Station, the construction of which was authorized in June 1959. The clearing of the 2,300-acre site on the eastern shore of Lake Huron began in February 1960, and the Station is scheduled for completion by mid-1964. Provision has been made for two 200-MW. units, but at present only one unit *Candu* (Canadian deuterium uranium) has been authorized and is under construction.

The third nuclear project, called *Ocdre* (organic cooled, deuterium moderated, reactor experiment), consists of the development of a nuclear power reactor of medium size which it is hoped will prove attractive to industrial concerns. A preliminary report on the design of such a reactor, which was to be available in August 1960, is to include an estimate of cost of the construction of an experimental reactor. The fourth project is devoted to the study of information relating to small nuclear plants suitable for use in remote regions of Canada.

At the Chalk River Research Establishment both the *Nry* and *Nru* reactors were in routine operation during the year, being fully occupied with research experiments, the production of radioisotopes and plutonium, and engineering testing. The several 'loops' in the reactors have been used by both the United States Atomic Energy Commission and the United Kingdom Atomic Energy Authority. The

* Atomic Energy of Canada Limited. Annual Report, 1959-1960. Pp. 36. (Ottawa: Queen's Printer, 1960.) 25 cents.

two small experimental reactors, *Zeep* and *Pt*, were also in constant operation, and a new zero energy, heavy-water moderated reactor, *Zed-2*, is being constructed and is nearing completion. One of the important lines of fundamental research carried out at Chalk River is the investigation of the structure of the atomic nucleus for which special facilities, such as the experimental reactors and particle accelerators, are provided. During the year under review major ancillary equipment was added to the 10-MeV. tandem accelerator for this particular investigation. In the Physics Division a new spectrometer, which employs the neutron beam from the *Nru* reactor as a probe to examine the forces holding together liquids and solids, was installed. The Research Chemistry Branch was mainly concerned with investigations on the breakdown of molecules exposed to intense radiation and the bombardment of metals with heavy ions. Fuel development, the physical properties of reactor materials, field tests of the method of disposal of fission products by fixing them in glass, and the development of new radiation monitoring instruments, including a tiny radiation detector which uses semiconductors, were some of the applied research problems investigated by the research establishment.

The directors and management of Atomic Energy of Canada Limited gave consideration during the year to the long-range expansion of research and development in the field of atomic energy, and recommended that Chalk River should not continue to expand, but that a new site should be selected at which future expansion could take place. In October 1959, the Government announced the establishment of a new research and development centre in Manitoba, on the east bank of the Winnipeg River between

Seven Sisters and Lac du Bonnet, to be known as the Whiteshell Nuclear Research Establishment. The first major facility to be provided at the new site is likely to be the *Ocdre* reactor. During October also, Canada and Euratom signed an agreement for co-operation in the peaceful uses of atomic energy and a technical agreement for a joint programme of research and development in heavy-water reactors. A group of Euratom industrialists visited Canada in the autumn to see the various atomic energy facilities. Close co-operation with the United Kingdom Atomic Energy Authority and the United States Atomic Energy Commission continued, as well as with the authorities in Australia, Japan and Pakistan. The number of staff from other countries attached to Atomic Energy of Canada Limited during the year was sixty-two, and was limited only because of lack of working and housing accommodation. The construction of the Canada-India reactor at Trombay, India, is now essentially complete and the initial start-up is scheduled for mid-1960.

The report concludes with the financial accounts of Atomic Energy of Canada Limited and with details of the Commercial Products Division which is responsible for the production, planning, processing and marketing of the radioisotopes produced in the Chalk River reactors. More than half the curies of radioactivity sold by Canada has been for the cobalt therapy machines for the treatment of cancer which were originally developed in Canada. One hundred and eighty-five machines have been installed in thirty countries. Another device recently developed is the *Gammacell* 220, which is a portable facility for the gamma-irradiation of materials, and fourteen of these units are in service in eight countries.

CONCENTRATION OF PLANKTON PIGMENTS IN AUSTRALIAN WATERS

ESTIMATIONS of the quantity of plankton pigments are widely used as a measure of the biomass of phytoplankton. They have achieved this popularity through the ease and accuracy of the chemical estimation, and they give results more reliable than most other techniques. However, as G. F. Humphrey emphasizes in a recent paper issued by the Australian Commonwealth Scientific and Industrial Research Organization, they have many disadvantages. For example, there is a variable and uncertain relationship between pigments and the chemical composition of the organism, and so they are a poor measure of, say, the cellular carbon. Nevertheless, the pigments are the potential absorbers of the energy used in photosynthesis and the widespread usage of one particular method commends it further (Division of Fisheries and Oceanography. Technical Paper No. 9: The Concentration of Plankton Pigments in Australian Waters. Pp. 27. Melbourne: Commonwealth Scientific and Industrial Research Organization, 1960).

The author, Dr. G. F. Humphrey, who is chief of the Division of Fisheries and Oceanography, has gone to some length in perfecting a satisfactory modification of the Richards and Thompson technique for pigment measurements. He has also ascertained the

precision obtained with the method, and for the analyses this amounts to ± 10 per cent, but the variation between replicate plankton samples is much larger and particularly at greater depths it is shown even to exceed previous estimates of ± 33 per cent.

The results described were obtained mainly from the Tasman Sea and in particular from two stations at 50 and 100 m. depth off Sydney. The ratios of the pigments varied during the year, with either chlorophyll *a* or *c* predominating. Chlorophyll *c* was frequently in excess and it appeared to be a pigment of major importance in the deeper waters. It should be mentioned, however, that the units used to express chlorophyll *c* values cannot be compared in absolute terms with the milligrams of chlorophyll *a*, for the specific absorption coefficient of pure chlorophyll *c* is not yet known and the determination of the actual weight of chlorophyll *c* is therefore not possible.

No smooth seasonal variation is evident in the results, but from late winter to late summer there were a series of sharp increases in pigment. There is some evidence that these peaks may be correlated with the prevailing hydrological conditions. The depth distribution suggests that the inorganic

phosphate content was inversely proportional to the chlorophyll, but neither nitrate nor total phosphate showed any correlation with the pigments.

The quantities of pigments found off Sydney covered the range found on more extensive cruises in the Coral and Tasman Seas and in the Indian Ocean. On these cruises the importance of chlorophyll *c* was again evident.

The results described in this paper are the first detailed observations of plankton pigments from Australian waters, collected in the extensive oceanographical programme which the Commonwealth Scientific and Industrial Research Organization in Australia is now undertaking, and they form an interesting basis for comparison with other regions.

R. I. CURRIE

CENOZOIC MAMMALS IN NORTH AMERICA

JUST over one hundred years ago Charles Moore, an amateur geologist of Bath, washed and sieved three tons of clay to obtain 30 multicusped teeth—the clay was a Rhaeto-Liassic fissure infilling and the teeth were of *Microlestes*, and they remain to-day almost the only record of this rare group of animals astride the frontier that separates mammals and reptiles.

Despite this promising beginning, few vertebrate palaeontologists have taken to the labours of washing and sieving on a big scale. Dr. McKenna has been one and it has paid handsome dividends; the washing and sieving of Wasatchian claystones and sandstones has yielded him 11,000 complete mammal teeth from a formation otherwise almost barren, and a horizon astride the Eocene and Palaeocene all too poorly known. The complete dissociation of the remains is a considerable limitation of the technique and Dr. M. C. McKenna does not appear to have attempted any concentrating methods, the fossils being hand picked from sieved fractions (University of California Publications in Geological Sciences. 37, No. 1: Fossil Mammalia from the Early Wasatchian Four Mile Fauna, Eocene of Northwest Colorado. Pp. 1-130. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1960.) 2.50 dollars).

A fauna of 58 species from 12 mammalian orders is described; these include four multituberculates, a marsupial, several primates and insectivores. The fauna shows close similarity with those of early Gray Bull fauna of Wyoming, though there are notable

absentees, and is considered early Wasatchian, that is, basal Eocene. The paper has no plates, but the text-figures are ample and exceptionally clear.

Pantodonta is an order of mammals the systematic study of which is fraught with difficulties; while distinction as an order is clear, the internal and external affinities remain debatable. Recent work by Dr. E. L. Simons is confined largely to the Palaeocene species of North America, albeit this comprises most of the described forms; the European Eocene and Asiatic Oligocene forms are mentioned in his discussions (*Trans. Amer. Phil. Soc.* (New Series), 50, Part 6: The Paleocene Pantodonta. Pp. 99. (Philadelphia: American Philosophical Society, 1960.) 2.50 dollars). Detailed diagnoses are given for North American Palaeocene species only. The post-cranial skeleton is described for most genera where it is known, with differences noted, but few comments on their significance: although approximately half this paper is devoted to skeletal anatomy, there is only one illustration of pelves. The wealth of material available makes it difficult to accept the quotation "they [Pantodonta] defy interpretation of their mode of life because they are so totally unlike anything now living"; they are no more remote than Titanotheres and mammal-like reptiles.

Biostratonomic work threw little light on the ecology of the pantodonts; this is not surprising since their life habitat was probably quite different from their place of entombment. Concerning the relations to other orders, the author restates the main arguments used by earlier writers. R. J. G. SAVAGE

EARTH SATELLITE OBSERVATIONS AND THE UPPER ATMOSPHERE

Temperature Inversion in the F1-Layer

SUFFICIENTLY reliable values of atmospheric density—including the diurnal variations—in altitudes 200–700 km. have been derived from the variations of the acceleration of artificial Earth satellites¹⁻³. Measurements from rockets^{4,5} gave density values up to about 200 km.

The densities obtained from rocket measurements and the satellite data could not be represented satisfactorily by a single curve with monotonically varying gradient. Therefore, H. K. Kallmann⁶ suggested a model which contains a 'wiggle' in the logarithmic density curve at altitudes 150–200 km. It is model C in her paper.

From the data⁷ from satellites 195882 (*Sputnik 3*) and 1959ζ (*Discoverer 6*), it now became possible to derive the exact form of the 'wiggle'. Twenty values for atmospheric density at altitudes 180–235 km.

from the satellite 1959ζ and the numerous results from the satellite 195882 during August 1959–April 6, 1960, were available for this purpose. During this period the altitude of the perigee of the latter satellite decreased from 215 km. to 147 km. In order to eliminate seasonal effects, only values with $|\Delta\delta| = |\delta_{\pi} - \delta_0| < 60^\circ$ were used (where δ is declination, π is perigee, 0 is Sun).

The atmospheric densities were first derived according to a method described in detail in our earlier paper¹; that is, preliminary values for atmospheric density were computed using the scale heights of H. K. Kallmann's 'preliminary model'⁶. Then a linear approximation to the logarithmic density curve was derived graphically for altitudes where the major air drag on the satellite occurs. The gradient of this linear approximation was employed to determine the final atmospheric densities, so that we have an itera-

tion process. Because of the diurnal density variation, the gradient depends on local time. This was taken into account in the last step of the iteration.

Even the preliminary atmospheric densities derived showed a well-developed 'wobble' in the logarithmic density curve which varied only slightly in shape when changing to the final atmospheric densities. Finally, the atmospheric densities above 180 km. were corrected to a standard value of solar activity. It is based on a flux of solar 20-cm. radiation of $S = 170 \times 10^{-13}$ W./m.²c./s.

As has been shown in an earlier paper¹, the atmospheric densities are practically proportional to the flux of the 20-cm. radiation. This correlation was called the 'solar effect' or (better) 'effect of solar activity'. It has since been confirmed by L. G. Jacchia². The reduction was performed using the relation:

$$\Delta \log \rho = \log \rho_{\text{obs.}} - \log \rho = \log (S/170) \quad (1)$$

where ρ is the atmospheric density and S the solar flux at wave-length 20 cm. in units 10^{-13} W./m.²c./s. The measurements were obtained by the Heinrich-Hertz-Institut, Berlin-Adlershof. We used values averaged over ten-day intervals since the satellite data also represent averages over several days. Since the solar values showed little scattering about the standard value of 170 during the period of interest, the correction had little influence on the shape of the curve.

For the ratio of mass to area we used $m/A = 40.8$ gm.cm.⁻² for 195882 and $m/A = 12.9$ gm.cm.⁻² for 19597. From this follows $ACD/F/m = 0.0465$ cm.²/gm. and 0.154 cm.²/gm., where C_D is the drag coefficient and F a factor between 0.9 and 1.0 caused by rotation of the atmosphere, using the notation of D. G. King-Hele³. We found that the ratio of mass to area for the satellite 19597 gave atmospheric densities fitting those obtained from *Sputnik 3* very closely.

The computed atmospheric densities are shown in Fig. 1. The circles and triangles represent the densities obtained from the *Space Track Bulletins* of *Sputnik 3*. The circles marked the data for $|\Delta\delta| < 20^\circ$ and the triangles values for $20^\circ < |\Delta\delta| < 60^\circ$. The open symbols are day-time values (8-20 hr. local time), the filled symbols night-time values (20-8 hr.)

Below 170 km. the data of the Smithsonian Astrophysical Observatory deviate from the *Space Track* data. In this region the Smithsonian data are represented by crosses. The solid curve is valid for 14 hr. local time, the dotted curve for 6 hr. local time. Data from *Discoverer 6* are marked by vertical crosses.

The rocket measurements by LaGow *et al.*⁴ have been inserted in the diagram. The data were obtained from rocket launchings at Fort Churchill on July 29, 1957, 4.00 p.m. c.s.t. and October 31, 1958, 2.00 p.m. c.s.t., giving atmospheric densities at altitudes up to 210 km. and 188 km. respectively. These results, too, were corrected for the solar effect. The

daily averages of the 20-cm. radiation were $S = 256$ and 188 after calibration (letter from the Heinrich-Hertz-Institut).

As will be seen, the 'solar effect' originates in the region of the 'wobble' (F_1 -layer of the ionosphere) as a result of absorption of ultra-violet radiation. At 150 km. the influence on the atmospheric density becomes negligible. Thus the rocket data for $h \gg 180$ km. were corrected using equation (1); the data for $150 < h < 180$ km. were corrected using the following relation:

$$\Delta \log \rho = \frac{1}{30} (h_{\text{km.}} - 150) \cdot \log (S/170) \quad (2)$$

Thus we obtained an increase in the correction from 0 at 150 km. to the full value at 180 km.

The agreement between the rocket data and the curve is excellent. In interpreting the data, however, one has to take into account the position of the rockets in 59° north latitude, with $\Delta\delta = 40^\circ$ on July 29, 1957, and $\Delta\delta = 73^\circ$ on October 31, 1958.

The very close correlation between atmospheric density variations ($h > 180$ km.) and the solar 20-cm. radiation emitted from the hot condensations of the solar corona points to the fact that the origin of the solar effect may lie in the absorption of solar ultra-violet radiation, which is also part of the thermal emission of the hot condensations. The Lyman alpha line of He⁺ (304 Å.) may be mainly responsible for that, because of the high ionization potential of helium. H. E. Hinteregger *et al.*⁵ were able to measure the absorptions of the He⁺ line in altitudes 150-210 km. from a rocket on March 12, 1959. From their results we find that the Earth's atmosphere has at 304 Å. an 'optical thickness' $\tau \approx 0.1$ at 210 km. but $\tau = 1$ at 160 km. The increase in optical thickness is almost linear in the $\log \tau, h$ diagram for altitudes 210-150 km. At 150 km. the He⁺ line is almost completely absorbed.

From the atmospheric density curve between 180 and 200 km. we find a temperature inversion in the F_1 -layer. The quantitative representation of the

Fig. 1. Atmospheric densities at altitudes 150-230 km. above the Earth ellipsoid. The solid line refers to 14 hr. local time, the dotted line to 6 hr. local time. The results were obtained from the satellites 195882, 19597 and the rocket launchings (ref. 5) of July 29, 1957, and October 31, 1958. The results from 195882 are subdivided into three groups according to their $\Delta\delta$ -values ($\Delta\delta = \delta_{\text{sun}} - \delta_{\text{sat}}$) (where δ is declination, π is perigee, $\odot$ is Sun). Open symbols give day-time values (8-20 hr. T.L.T.); filled symbols give night-time values (20-8 hr.)

temperature will be given elsewhere¹⁰. Because of the small heat conduction at 200 km. the density curve changes little between day and night (see Fig. 1).

It is not possible at present to decide whether solar ultra-violet radiation as well as the solar He⁺ line and solar X-ray radiation contribute to the heating of the F1-layer. Furthermore, heating by a steady flux of solar corpuscular radiation may be expected at 200 km. according to L. G. Jacchia's observations on satellite 195881 during the magnetic storms of July 1958 and September 1958. The diurnal variation of atmospheric density may indicate a contribution of corpuscular radiation to the heating (see ref. 11, Fig. 1). The increase in density seems to start before sunrise; that cannot be explained by electromagnetic radiation. However, because of the large scattering of the values, this result seems unreliable.

A second 'wiggle' depending on solar activity may be expected in the E-layer. It remains to be shown whether it has an observable value. A third 'wiggle' could be expected at 300–500 km. (F2-layer). It will be smoothed out by the large heat conductivity that has been deduced by M. Nicolet¹². This problem will be discussed in more detail in the following communication¹¹.

We are grateful to Dr. H. K. Kallmann, who suggested this problem, and to Mr. D. G. King-Hele for discussion of the data of *Discoverer 6*.

Diurnal and Seasonal Density Variations in the Upper Atmosphere

CONTINUING our earlier investigations^{1,2}, we have been able to derive the diurnal and seasonal density variations at altitudes of 210, 562 and 660 km. from variations in the acceleration of the satellites 195882 (*Sputnik 3*), 1959α1 (*Vanguard 2*) and 195882 (*Vanguard 1*). The computation of atmospheric densities by an iteration process has been described in the preceding communication and will be given in detail in a subsequent publication³. The air densities given in Figs. 1–3 are the final values obtained after the last step in the iteration process.

The numerous values of atmospheric density from satellite 195882 were grouped according to their dependence on $\Delta\alpha$ and $\Delta\delta$ respectively since the variations of density are relatively small at 210 km. above the Earth ellipsoid. The differences $\Delta\alpha$ and $\Delta\delta$ are defined by $\Delta\alpha = \alpha_\pi - \alpha_\odot$, $\Delta\delta = \delta_\pi - \delta_\odot$ (where α is right ascension, δ is declination, π is perigee, $\odot$ is Sun).

The diurnal variation of density is a function of $\Delta\alpha$ and thus of true local time. Since during the lifetime of the satellite $\Delta\alpha$ traversed 360° eight times, the group averages of the diurnal variations are taken from different dates within the period May 15, 1958–October 1, 1959. Observations of the last six months of the satellite, during which its perigee traversed the 'wiggle' of the F1-layer, were not included in the derivation of the group averages. The seasonal effect is a function of $\Delta\delta$. The group averages are plotted in Fig. 1. The diurnal variation curves for $\Delta\delta = 0^\circ$ and -40° were obtained with the aid of a special adjusting method using all group averages.

The variation of the atmospheric density at 562 km. above the Earth ellipsoid is plotted in Fig. 2. These results were obtained from satellite 1959α1, and each

Fig. 1. Diurnal and seasonal variations in atmospheric density at 210 km. derived from observations of the satellite 195882. The lower α -scale gives true local time, the upper $\Delta\alpha = \alpha_\pi - \alpha_\odot$. The parameter of the curves is $\Delta\delta = \delta_\pi - \delta_\odot$, where α is right ascension, δ is declination, π is perigee, $\odot$ is Sun.

Fig. 2. Variations in atmospheric density at 562 km. above the Earth ellipsoid derived from the observations of satellite 1959α1. Scales as in Fig. 1.

Fig. 3. Variations in atmospheric density at 660 km. derived from the observations of satellite 1958 β 2. Scales as in Fig. 1

one is plotted. They are derived from the orbital elements of the Smithsonian Astrophysical Observatory and the dP/dt values by L. G. Jacchia⁴.

The variation of the atmospheric density at 660 km. was obtained from the orbital elements of the satellite 1958 β 2 (Fig. 3) (Orbital elements by NASA Computing Center, dP/dt values by L. G. Jacchia⁵). Each dot represents a group average. All diurnal variation curves have similar shapes, especially at high altitudes. The peak of density is reached at about 14 hr. true local time. Then a steep decline follows until sunset. During the night, the density continues to decline though more slowly and almost linearly. After sunrise the curve begins to rise steeply until it reaches its peak.

The amplitude of the variation increases with increasing altitude. Above 300 km. it becomes the most important characteristic of the atmospheric model. In Fig. 4 the variation of atmospheric density is plotted against true local time for the zone $|\Delta\delta| < 20^\circ$. The model was obtained using the curve shown in Fig. 2. This curve was selected because it was obtained from results between February 24, 1959, and March 20, 1960. During this period, the 20-cm. observations obtained by the Heinrich-Hertz-Institut, Berlin-Adlershof, showed no intense drifts of long duration as was the case in 1958. An explanation of the drift in 1958 has not yet been given. M. Nicolet⁶ assumes that the drift results from instrumental errors; this means, however, that in order to understand the satellite observations one must postulate an important effect of unknown cause the variation of which corresponds to the variation in the 20-cm. radiation (see also L. G. Jacchia⁴).

The shape of the curves in Figs. 2 and 3 as functions of the position of the Sun (local time) shows clearly that the diurnal variation results from the absorption of electromagnetic radiation (ultra-

violet-radiation) and from heat conduction, which is very rapid at high altitudes. The diurnal variations which occur at altitudes higher than 250 km. cannot result from the heating by absorption of the He⁺ line 304 Å. at 200 km. because heat conduction is very slow at this altitude. Thus one may conclude that a further absorption of high-energy solar radiation occurs at altitudes 300–500 km., possibly in the F₂-layer. Because of the rapid heat conduction, no well-developed 'wiggle' is to be expected. The day-time heating simply results in a larger curvature of the logarithmic curve of density. This may be seen in comparing the curvatures above 400 km. for 14 hr. and 6 hr. in Fig. 4. The effect of both heating and heat conduction results in the 'fan shape' of the density model (Fig. 4).

The isothermal atmosphere which is caused by rapid heat conduction begins above 500 km. The temperature there is a function of local time analogous to the density function. One may suppose that the heating results mainly from the absorption of the helium line at 584 Å. at altitudes of 300–500 km. The line was barely detectable at 210 km. according to measurements by H. E. Hinteregger *et al.*⁷. Measurements of the solar ultra-violet radiation and the X-ray spectrum between 300 and 500 km. are urgently needed. At the same time, measurements of the helium content of the upper atmosphere would be highly desirable.

The diurnal variation of density for $|\Delta\delta| > 20^\circ$ gives an insufficiently uniform picture. Furthermore, from the above theory we must expect the density to be a function of geographical latitude as well as $\Delta\delta$.

The physical condition in the upper atmosphere may be summarized in the following simplified picture: The 'solar effect' originates in the F₁-layer as a result of heating by the solar He⁺ line at 304 Å. This explains the good correlation between density variations above 200 km. and solar decimetre radiation

Fig. 4. Diurnal variations of the atmospheric density at altitudes 150–700 km. above the Earth ellipsoid for $|\Delta\delta| < 20^\circ$. All values are corrected to mean solar activity (solar flux of 20-cm. radiation $S = 170 \times 10^{-22}$ W./m.² c./s.). The parameter of the curve gives the true local time. In addition to the satellites mentioned in the text, we used 1958 α and 1958 β in computing this atmospheric density model

(3–30 cm.). The period of the density variations agrees largely with the rotational period of the Sun. The heating of the *F*1-layer determines the boundary conditions for the upper atmosphere at 210 km. This explains why the logarithmic curves for density appear to be shifted parallel as a function of 20-cm. radiation (see ref. 1, Fig. 10). The diurnal variation of density at 210 km. is only a few per cent. Absorption of solar electromagnetic radiation in the *F*2-layer together with the large heat conductivity cause the intense diurnal density and temperature variations above 300 km. ('fan shape' of the air density model, Fig. 4).

We gratefully acknowledge the continuing dispatch of 20-cm. data by the Heinrich-Hertz-Institut, Berlin-Adlershof, prior to publication. We are also indebted to Dr. H. K. Paetzold for unpublished dP/dt values of *Sputnik* 3. Furthermore, we wish to thank the Space Track Center and the Smithsonian

Astrophysical Observatory for supplying the orbital elements.

SOME GEOCHEMICAL ASPECTS OF A COLUMBITE-BEARING SODA GRANITE FROM SOUTH-EAST UGANDA

By DR. O. VON KNORRING

Research Institute of African Geology, University of Leeds

AS part of the exploratory programme of the Research Institute of African Geology in the University of Leeds, a unique radioactive soda granite from the Lunyo area in south-east Uganda has been investigated. This granite was first recorded and named the Lunyo granite by Dr. K. A. Davies¹, a former director of the Uganda Geological Survey. Late in 1961 a number of specimens of the Lunyo granite were examined in this Institute, and at the request of Dr. Davies a mineral separation was carried out in order to analyse an unusual mica in the granite. The mica was identified as zinnwaldite, rich in lithium and with an exceptionally high fluorine content. During 1966 the concentrates of the Lunyo granite were re-examined, and in addition to the main magnetite and zircon, columbite, cassiterite and thorogummite were found. The discovery of these important accessories prompted a closer investigation of the Lunyo area, and a summary of this work is communicated here.

The general geological configuration of south-east Uganda has been previously described by Davies¹. Subsequent geological observations have shown that the main rock types occurring within this region can be conveniently correlated with the Nyanzian rocks on the eastern side of Lake Victoria in Kenya. The minimum absolute age for the Nyanzian as deduced from lead isotope determinations in galena is $2,200 \pm 150$ million years. The rocks of the Nyanzian System are therefore comparable in age with the oldest rocks known from the Precambrian.

The area under discussion lies in the south-eastern-most corner of Uganda, bounded by the Kenya border to the east and Lake Victoria to the south. Granitic and dioritic rocks constitute the main geological element, and are seen to be intrusive into remnants of older supracrustal rocks comprising leptytes and amphibolites with an east-west trend.

The Lunyo granite is exposed in a few separate units occupying a total area of some 10 sq. miles.

The following tentative geological succession has been established in the area: 1, leptytes and amphibolites; 2, granodiorites; 3, Lunyo granite; 4, Masaba granite; 5, late doleritic dykes.

The leptytes are the metamorphic equivalents of Precambrian acid volcanics, usually of rhyolitic-dacitic composition. Banded structures consisting of coarse- and fine-grained layers suggesting alternating lava and tuff material are frequently seen. Among the leptyte varieties there may be both soda and potash extremes, as well as rocks with a silica content greater than 80 per cent. The leptytes in this area are generally porphyritic meta-dacites and are dominantly soda-bearing. The highest metamorphism attained corresponds to the amphibolite facies. The volcanic character of these rocks is very apparent and, in places hypabyssal equivalents, either fine-grained felsites or coarser feldspar porphyries, are observed. Some of the leptytes have conspicuous corroded phenocrysts of sapphire-blue quartz, a feature which persists over wide areas. Pyrite and pyrrhotine mineralization is widespread among the leptytic rocks.

The meta-rhyolites have been observed only in isolated hills rising above the normal flat terrain. They are extremely siliceous rocks, and in their present metamorphic state resemble fine-grained sericite schists of sedimentary origin; however, some exposures show distinct igneous flow structures, and in thin sections the rocks are seen to contain corroded bipyramidal crystals of quartz. In places, quartzites associated with these latter rocks and especially those which bear andalusite or are interbanded with graphitic shales and haematite ore, may well have formed under different conditions, for example,

alternating sedimentation of colloidal silica, clay and iron hydroxides in water.

The amphibolites are either interbanded with the leptytes or form separate lenticular bodies. In some parts they occupy larger areas, for example, Bulamba and Isindi hills, and are frequently accompanied by coarse doleritic types. At several exposures pillow structures are developed locally, and some thin sections exhibit distinct flow texture.

The granodiorites form a characteristic group of rocks, and in one case a lenticular body extends for several miles along the southern boundary of the Lunyo granite. The granodiorites consist of lath-shaped crystals of zoned plagioclase, together with larger reddish grains of microcline-perthite, amphibole and smaller amounts of biotite and quartz. Contacts between the granodiorite and the leptytes indicate a later emplacement of the former rocks, while pegmatite veinlets which apparently have been derived from the Lunyo granite are seen to intersect both the leptytes, amphibolites and the associated granodiorites.

The main type of the Lunyo granite as found in the Lunyo hill area is a leucocratic, medium-grained rock, with a distinct foliation produced by the parallelism of ellipsoidal quartz grains, especially clearly seen on the weathered rock surface.

Observations in the field show, however, considerable variations both in colour and size of grain, and often the granite appears to be porphyritic with large, rounded phenocrysts of quartz, angular porphyroblasts of feldspar and aggregates of mica set in a fine-grained matrix of albite.

Direct contacts with surrounding granites or other rock types have not been observed. In many places within the Lunyo granite, pods and schlieren of gneiss are common. These are at times of considerable size and consist mainly of a fine-grained greenish-yellow mica (phengite) with some feldspar, quartz and variable amounts of fluorite. A partly greisenized Lunyo granite contains some 4 per cent fluorite. Pegmatites and aplites are common associates of the granite. Indeed, in places they are so numerous that the rock resembles a veined gneiss. The pegmatites occur as sheets or bands which are either cross-cutting or conformable. They are not uniform in thickness, but pinch and swell to various degrees. Zoning has been observed in some cases, but on the whole is rare. The pegmatites consist chiefly of a coarse-grained white or red microcline-perthite with

varying amounts of quartz and fine-grained albite and only occasionally some mica is present. The aplites are intermixed with the pegmatites and are composed of the same minerals, but the soda/potash ratio is much higher. Microscopic examination of the Lunyo granite shows ovoid-shaped grains of quartz with highly undulose extinction and often with inclusions of minute albite laths at times in concentric arrangement. The microcline porphyroblasts almost always contain inclusions of albite, commonly aligned and forming a regular pattern, and stringers of albite in a flame-perthite fashion. Grains of a crypto-perthite, thought to be anorthoclase, also have been noted. Fine-grained albite constitutes the ground-mass, and frequently the laths are seen to be in parallel orientation. Zinnwaldite, which is the main mica of the rock, shows a distinct light-green to blue-grey pleochroism. A dark-green mica is locally present forming spherical aggregates.

The following accessory minerals have been identified so far: magnetite, columbite, cassiterite, zircon, thorogummite, fluorite and pyrite in the granite, and in addition to these betafite, kasolite, galena, zincblende and cerussite in the pegmatites. An interesting feature is that both the granite and the associated pegmatites, aplites and greisens contain practically the same rare-mineral assemblages.

The Masaba granite borders the Lunyo granite and the meta-volcanics to the north, east and south. The granite intrudes in the leptytes and the amphibolites and forms a contact zone of hybrid rocks which retain many of the textural features of the original volcanics; they also include xenoliths of leptytes and amphibolites. There does not appear to be any genetical relationships between this granite and the Lunyo granite proper, and it is perhaps significant that pegmatites are totally absent.

Late dolerite dykes cut all the previous rocks. It is often difficult, however, to distinguish these dykes from older doleritic rocks associated with the amphibolites.

A series of chemical and spectrographic analyses have been made on rocks from the Lunyo area, including various types of the Lunyo granite, aplites, meta-volcanics, granodiorites, amphibolites and other granitic rocks from the surrounding area, and a part of these results is reproduced in Table 1.

The outstanding rocks, from a geochemical point of view, are the Lunyo granite, together with the

allied rocks within its boundaries. The chemical composition of the Lunyo granite, analysis 1, shows some affinities to the metasomatic late-kinematic ideal granites as defined by Eskola³, providing the alkalis are reversed. Geochemically, there are marked similarities with the Nigerian younger granites, especially with the late suite of albite-riebeckite granites⁴.

Among the major constituents, alumina is much higher than in ordinary granites. This is mainly due to the high soda, as there is no corresponding increase in lime. Coupled with the high soda and potash, the sum of the normative feldspars is more than 70 per cent, while the albite component is approximately 60 per cent. The cafermics are exceptionally low, and usually amount to less than 1 per cent.

Among the minor elements, lithium and rubidium are comparatively high. Spectrographic estimates of lithium and rubidium indicate that the amounts of these constituents are higher than is usual for granitic rocks, apart from those of the pegmatitic phase. Lithium is contained in zinnwaldite and other micas, and rubidium is concentrated mainly in the microcline-perthite of the pegmatites, where the rubidium content is approximately 1 per cent. Fluorine is constantly present and is abundant in the fluorite-bearing granite. In the Lunyo granite most of the fluorine is accommodated in the zinnwaldite, which carries 8 per cent fluorine. The content of beryllium is low and beryl has not been met with in the pegmatites of the area. Lead and zinc are distinctive trace elements of this complex and both are represented by independent minerals: galena, sphalerite (yellowish-green in colour), cerussite, kasolite (a lead-uranium-silicate) and an unidentified lead-uranium mineral. All these minerals have been introduced during a late stage and at relatively low temperatures. There is a much lower concentration of the rare earths as compared with the Nigerian province; consequently monazite and xenotime have not been found. The content of the trivalent gallium, however, is greater than average. Zirconium, tin and thorium are represented by the accessories zircon, cassiterite and thorogummite. The latter mineral is found in various stages of alteration and may be green, yellow, orange or brown in colour. The titanium content is exceptionally low and no independent titanium minerals have been noted. The high niobium content is a characteristic feature of the Lunyo granite and its associated pegmatites, aplites and greisens. In the granite itself the niobium content in terms of columbite varies from 0.05 to 0.1 per cent, in the greisens there is approximately 0.1 to 0.2 per cent, and in the aplites and pegmatites the columbite may be as high as 0.5 per cent. These columbite values

are comparable with those of the Nigerian younger granites⁴. The Nb₂O₅/Ta₂O₅ ratio is about 13 to 1. Another niobium mineral, betafite, has been identified from various pegmatites.

In addition to the conspicuous deficiency of titanium, there is also an apparent lack of boron and phosphorus. Tourmaline and apatite appear to be absent in the Lunyo granite and its associates, and even the greisens are devoid of these minerals.

When the values for trace elements of the Lunyo granitic suite are compared with those of the surrounding rocks, the former show a completely distinct geochemical pattern (Table 2).

The characteristic textural features of the Lunyo granite, together with its position within the belt of porphyritic volcanics, strongly suggest some genetic relationship with the latter rocks. The granite is considered to have been formed by metasomatic granitization of soda-rich volcanics of the Butenge type, and the unique mineralization involving lithium, fluorine, zinc, lead, zirconium, tin, thorium, niobium and uranium in the form of accessory minerals is believed to be connected with the granitization process. The metasomatism appears to have involved little addition of soda, but potash was certainly introduced, particularly during the later stages of granitization now marked by the dominantly microcline-rich pegmatites and micaceous greisens.

The Lunyo granite, together with its pegmatites, aplites and greisens, are distinctly radioactive over large areas. The main cause of this radioactivity was initially attributed to the accessory thorogummite, but recent observations have shown that, among the accessory minerals, kasolite and betafite are of common occurrence and thus contribute to the radioactivity. A sympathetic relationship seems to exist between the important minor accessories and the radioactivity observed. Thus higher radioactivity not only denotes an increase in radioactive minerals but also indicates higher concentrations of columbite.

This work has been undertaken in close collaboration with the Geological Survey of Uganda. I am indebted to Mr. A. Cawley, director of the Geological Survey, for his assistance during field-work and permission to publish this communication.

ULTRASONIC DEGRADATION OF WOOL AND HAIR

By DR. J. H. BRADBURY

Division of Textile Industry, Wool Research Laboratories, Commonwealth Scientific and Industrial Research Organization, Geelong, Victoria, Australia

ULTRASONIC vibrations have been used for the disruption of cells¹, micro-organisms², and for the modification of soluble proteins and amino-acids³⁻⁵. The evidence on wool is conflicting, since it has been reported that virgin wool is not degraded by ultrasonics^{6,7}, although shrink-proofing can be effected by this means⁸, and Andrews⁹ has since found that cuticular material is liberated. Because of the need for a purely mechanical method of degradation of the fibre (other than the laborious method recently developed^{10,11}), it was decided to investigate this possibility. It is reported here that wool and hair can be degraded mechanically by ultrasonic treatment, with no appreciable amount of chemical attack, into cuticle material and cortical cells.

Two different types of ultrasonic instruments were used. The first was a 60-watt, *MSE*-Mullard ultrasonic disintegrator in which waves of 16–24 kc./s. were transmitted by a $\frac{3}{4}$ -in. diameter stainless steel probe immersed directly in the solution containing the sample. Samples of wool and hair (0.05–1 gm.) were treated at $< 35^\circ$ about 1–4 cm. below the probe, which disintegrated slowly in aqueous solutions. The second was a 60-watt, Narda Ultrasonics Corporation, Sonblaster, series 600, in which the contents of a 3-litre capacity stainless steel tank were treated with ultrasonics at 40 kc./s. Samples of up to 10 gm. of wool and hair were treated in about 1-litre of solution which was kept at $< 30^\circ$ by a cooling coil.

After treatment the residual fibres were dried, snippets were cut in a representative manner and mounted in 'Sellotape'^{12,13}. These were examined under the microscope and < 200 classified into four different groups as follows: (0) scales undamaged, (1) slight removal of scale edges, (2) considerable removal of scale edges, (3) complete removal of scale edges. The percentage of fibres in each category was multiplied by the number in brackets and the figures summed to give a weighted total indicative of damage to the cuticle.

The milky solution obtained after treatment was centrifuged, and if the Mullard instrument had been used, metal particles were sedimented by centrifugation in 2 *M* potassium dihydrogen phosphate, 2 *M* dipotassium hydrogen phosphate solution while the protein remained suspended. The latter was weighed, examined microscopically and in a few cases amino-acid analyses were carried out by the dinitrophenylation method¹⁴.

Samples of virgin wool ranging from Merino 90's to Lincoln 36's, and human hair were cleaned¹⁴ and 3-gm. samples treated in the Sonblaster for 16 hr. in 500 ml. distilled water. A yield of 0.6 per cent of degraded material was obtained from each of the four samples of wool and 1.5 per cent from the human hair. The material from wool and hair consisted of about 90 per cent of small flat pieces of cuticle material and about 10 per cent of needle-like cells of sizes up to that of cortical cells. The treated fibres were examined microscopically and there was a gradation from no

apparent damage with Merino 90's to a value of 62 for Lincoln 36's and 103 for human hair. This would be expected in view of the progressive decrease in the surface area to weight ratio of the fibres in this series. It is not clear why the cuticle of human hair breaks down more rapidly than that of wool, particularly as the former overlap along about 5/6 of their length compared with only about 1/6 for Lincoln wool¹⁵.

Three-gm. samples of Lincoln 36's top were treated for 2 hr. in the Sonblaster in 500 ml. of solutions buffered at pH 1, 3, 5, 7, 9 and 11. The percentage yields of degraded material were 0.1, 0.1, 0.2, 0.4, 0.6 and 0.6 respectively. The rate of breakdown was not increased by treatment in concentrated ammonia or hydrazine hydrate but was rapid in 0.1 *N* sodium hydroxide, with considerable chemical degradation of the wool. Treatment in aqueous solutions of lithium bromide (100 per cent w/v), guanidine hydrochloride (50 per cent w/v), urea (sat.) or glacial acetic acid, dichloroacetic acid, formamide or dimethyl formamide produced only small changes in the amount of breakdown, but there was a large increase in 98 per cent formic acid. Breakdown was slight in organic solvents such as *n*-butanol, ethanol and a petroleum fraction, b.p. 150–200°.

Samples of Lincoln 36's top chemically modified by acid chlorination, hydrogen peroxide, reduction with sodium hydrogen sulphite or treatment with alcoholic sodium hydroxide showed no greater rate of ultrasonic breakdown during 24-hr. treatment in water using the Mullard instrument than the untreated top. Also wool from the tip of the fibre showed no difference in behaviour from that taken from the base.

Two samples of human hair treated for 4 hr. and 40 hr. in the Mullard instrument in water produced material in about 0.3 and 4 per cent yields respectively. On amino-acid analysis¹¹ it was found that the latter sample contained more Arg (26 per cent) Cys (29 per cent) and less Gly (19 per cent) than the former, but both were entirely proteinous. The differences may be due to the continuous mechanical degradation of the fibre, producing material of a continuously changing composition, and/or chemical degradation of the material. This point was resolved by amino-acid analyses on a finely powdered sample of Lincoln 36's top (obtained by grinding in a pestle and mortar under liquid oxygen) before and after a 40-hr. ultrasonic treatment as above. There was no detectable change in the amino-acid content after the ultrasonic treatment, hence the amount of chemical degradation was negligibly small.

The ultrasonic method should make possible a much more detailed investigation of the chemical composition and structure of the various cuticle layers of virgin and treated wools than has been possible by the descaling method¹¹ or by methods based on chemical degradation of the cuticle. It should also be possible to probe deeper into the wool fibre and separate chemically unchanged cortical cells for detailed investigation.

I thank Dr. M. W. Andrews for suggesting the possible usefulness of ultrasonics in the descaling of wool and Mr. H. Groll for assistance with the experimental work.

BIAS IN BASE-PAIR ORIENTATION IN DEOXYRIBONUCLEIC ACID

By DR. C. I. DAVERN

Division of Plant Industry, Commonwealth Scientific and Industrial Research Organization,
and Department of Microbiology, John Curtin School of Medical Research,
Australian National University, Canberra

A COMPLEMENTARY base-pair within a double-helical deoxyribonucleic acid molecule may be oriented in one of two ways. This article reports the finding of a relatively uniform bias in the orientation of the adenine-thymine complementary base-pair in human deoxyribonucleic acid.

KB cells¹ were cultured in the presence of 5-bromodeoxyuridine together with 5-fluorodeoxyuridine and uridine for 48 hr. at 36° C. Under these conditions a fraction of the cells undergo a single replication-cycle of their deoxyribonucleic acid². Since 5-fluorodeoxyuridine blocks the endogenous synthesis of the deoxyribonucleic acid thymine precursor, thymidylc acid³, all the newly synthesized deoxyribonucleic acid strands contained 5-bromouracil in the place of thymine. The caesium chloride density gradient analysis⁴ of the deoxyribonucleic acid from these cells revealed two bands of the acid (Fig. 1). The less-dense band (modal density = 1.702 gm.cm.⁻³) consists of unreplicated deoxyribonucleic acid molecules (that is, 'parental' acid). The more dense bimodal band (inter-modal density = 1.758 gm.cm.⁻³) comprises those molecules of deoxyribonucleic acid which have engaged in one cycle of replication in the presence of 5-bromodeoxyuridine, and thus contain density-increasing 5-bromouracil instead of thymine in their newly synthesized strands. They are 'hybrid' molecules with respect to their 5-bromouracil content. It is proposed that the bimodality of the hybrid deoxyribonucleic acid band arises from a uniform bias in the orientation of the adenine-thymine complementary base pair in most of, if not all, the deoxyribonucleic acid molecules in the cell complement.

By scoring the two possible orientations of a particular base-pair as +1 and -1, respectively, along a deoxyribonucleic acid molecule, the bias (β) for that base-pair is defined as the absolute value of the mean score for the molecule. Obviously, $0 \leq \beta \leq 1$.

The 5-bromouracil content of the two hybrid progeny molecules derived from a single replication in 5-fluorodeoxyuridine-5-bromodeoxyuridine of a molecule of deoxyribonucleic acid, will be different when it possesses an adenine-thymine bias greater than zero, providing the replication is semi-conservative⁵⁻⁷. Then the two hybrid molecules will have different buoyant densities.

Similarly, the 5-bromouracil hybrid progeny molecules derived from the semi-conservative replica-

Fig. 1. Spineco 'Analytrol' trace from an ultra-violet absorption photograph of the deoxyribonucleic acid concentration distribution obtained from human KB cells. Cells were cultured for 48 hr. in lactalbumin hydrolysate-Barie's saline with 15 per cent heat-inactivated human serum, containing 6×10^{-4} M 5-bromodeoxyuridine, 10^{-4} M 5-fluorodeoxyuridine and 10^{-4} M uridine. Cells were lysed by adding 0.05 ml. of 20 per cent aqueous sodium dodecyl sulphate to 3×10^6 cells in 1 ml. of physiological saline pH 8.5 and 0.01 M in ethylenediaminetetraacetic acid. A 0.5 ml. aliquot of this lysate made up to 57.7 per cent (w/w) with respect to caesium chloride, and centrifuged at 20° C. for 22.5 hr. at 44,770 r.p.m. The density gradient was 0.122 gm.cm.⁻⁴.

tion of a population of deoxyribonucleic acid molecules of heterogeneous base composition, but possessing a uniform adenine-thymine bias, will consist of two equal sub-populations differing in their mean 5-bromouracil content and hence differing in their mean buoyant density.

The mean buoyant density of the parental population (ρ_p) may be written in terms of mean base composition as:

$$\rho_p = \rho_0 + k_1 r_{GC} \text{ gm.cm.}^{-3}$$

where ρ_0 is the intercept at $r_{GC} = 0$, and r_{GC} is the mean molar ratio of guanine-cytosine, and k_1 is the density increment for the total substitution of adenine-thymine by guanine-cytosine.

Similarly, since the substitution of thymine by 5-bromouracil leads to a linear change in buoyant density⁴, the mean buoyant density of each population of hybrid progeny molecules (ρ_{H_1} and ρ_{H_2}) may be written as:

$$\rho_{H_I} = \rho_p + k_1 \left(\frac{1 + \beta}{2} \right) (1 - r_{GO}) \alpha \text{ gm cm.}^{-3}$$

and:

$$\rho_{H_{II}} = \rho_p + k_2 \left(\frac{1 - \beta}{2} \right) (1 - r_{GO}) \alpha \text{ gm.cm.}^{-3}$$

where k_2 is the density increment for total substitution of thymine by 5-bromouracil, β is the adenine-thymine bias and α the proportion of available thymine sites occupied by 5-bromouracil (here α is assumed to be 1). From the above equations adenine-thymine bias may be evaluated as:

$$\beta = \frac{\rho_{H_I} - \rho_{H_{II}}}{k_2(1 - r_{GO})\alpha}$$

For ease of computation the mode rather than the mean values of buoyant density and guanine-cytosine content were chosen to estimate the adenine-thymine bias of human KB cell deoxyribonucleic acid. Substituting 0.184 gm.cm.⁻³ for k_2 , 0.39 for r_{GO} , and 0.007 gm.cm.⁻³ for the difference in density between the two modes of the hybrid deoxyribonucleic acid band, one obtains 0.06 as an estimate of the adenine-thymine bias.

In each hybrid sub-population, the uniform incorporation of density-increasing 5-bromouracil is expected to decrease the buoyant density heterogeneity due to variation in guanine-cytosine content. The expected transformation factors (γ_I and γ_{II}) relating guanine-cytosine content to buoyant density for the two hybrid sub-populations (H_I and H_{II}) are respectively:

$$\gamma_I = 1 - \frac{(1 + \beta)k_2\alpha}{2k_1}$$

and:

$$\gamma_{II} = 1 - \frac{(1 - \beta)k_2\alpha}{2k_1}$$

For this experiment $\gamma_I = 0.02$ and $\gamma_{II} = 0.14$, using $k_1 = 0.100$ as given by Rolfe and Meselson⁸.

The variance of buoyant density in the parental deoxyribonucleic acid (σ_p^2) may be written as:

$$\sigma_p^2 = \sigma_T^2 + \sigma_D^2$$

where σ_T^2 is the variance due to thermal motion and σ_D^2 is the variance due to heterogeneity of base composition¹⁰. Similarly the expected variance of each hybrid sub-population can be written as:

$$\sigma_{H_I}^2 = \sigma_T^2 + \gamma_I^2 \sigma_D^2$$

and:

$$\sigma_{H_{II}}^2 = \sigma_T^2 + \gamma_{II}^2 \sigma_D^2$$

The expected variance of the hybrid distribution is therefore:

$$\sigma^2[H_I + H_{II}] = \sigma_T^2 + \left(\frac{\gamma_I^2 + \gamma_{II}^2}{2} \right) \sigma_D^2 + \left(\frac{\rho_{H_I} - \rho_{H_{II}}}{2} \right)^2$$

From Fig. 1 it can be clearly see that the variances of the hybrid sub-population would each be less than the variance of the parental deoxyribonucleic acid band, as one would expect.

The inequality of the modal concentrations of the hybrid deoxyribonucleic acid where the major mode is on the low-density side of the distribution is expected if the less-dense hybrid sub-population (H_{II}) has a γ_{II} value less than γ_I . This would imply a mean γ value less than 0. These expectations do not agree with the calculated values of $\gamma_I = 0.02$ and $\gamma_{II} = 0.14$. The discrepancy may arise entirely from the gratuitous assumption that the molecular volume is not affected by 5-bromouracil substitution. Indeed, the observed k_2 value (0.184 gm.cm.⁻³) exceeds the k_2 value (0.121 gm.cm.⁻³) expected from the mass increment due to 5-bromouracil substitution, assuming no change in molecular volume. Thus the appropriate k_1 value for computing the γ values may well be less than 0.100 gm.cm.⁻³.

Further studies have been made with the KB cell system using aminopterin instead of 5-fluorodeoxyuridine to block endogenous thymidylate acid synthesis⁸ and with HeLa cells using the 5-fluorodeoxyuridine-5-bromodeoxyuridine system. Bimodal distributions of the hybrid deoxyribonucleic acid were obtained in each case, confirming the postulate that human deoxyribonucleic acid contains a uniform bias in the orientation of its adenine-thymine base-pairs.

A more detailed account of this work will be published elsewhere.

CORRELATION OF VIRAL RIBONUCLEIC ACID AND PROTEIN COMPOSITION

By PROF. MARTYNAS YČAS

Department of Microbiology, State University of New York
Upstate Medical Center, Syracuse, New York

IN 1952 Dounce¹ suggested that the sequence of nucleotides in nucleic acid constitutes a code which determines the sequence of amino-acids in proteins. He did not, however, draw any conclusions as to how such a code could be deciphered. In 1954, without knowledge of Dounce's suggestion, Gamow² made a similar proposal, and pointed out that information on sequences of amino-acid might make it possible to determine the nature of the code, using elementary cryptographic methods.

About this time considerable information on amino-acid sequences of proteins became available. Numerous efforts were therefore made, mainly by Gamow and his collaborators, to solve the coding problem. These efforts failed³. It was found that all proposed solutions were either incompatible with known amino-acid sequences or were not subject to test by evidence then available.

The reason for this failure became clear as information on amino-acid sequences accumulated. Gamow's

original proposal assumed that enough information is available in nucleic acid to determine completely the amino-acid sequence in the corresponding protein. Since there are 20 kinds of amino-acids and only four nucleotides, at least three nucleotides would be needed to specify each amino-acid. As the nucleic acid was visualized to act as a template in protein formation, it was felt that there should not be too great a disparity in length between the nucleic acid and the protein produced. It was therefore assumed that neighbouring configurations of nucleotides, each determining an amino-acid, shared some of their nucleotides, and this, of course, would produce restrictions on possible sequences of amino-acids. 'Decoding' consisted, essentially, of a search for such restrictions, from which the nature of the code could be deduced. Unfortunately, as more amino-acid sequences were published, it was found that there were no restrictions, either absolute or statistical, on which amino-acid could neighbour one another³. It was therefore concluded that amino-acid determinants were not configurations of overlapping nucleotides⁴; but no further progress in decoding was possible by the method proposed by Gamow.

These negative results do not necessarily imply that all forms of the coding hypothesis are false, but do suggest the need for developing criteria other than those used by Gamow and his collaborators. It is my purpose to point out that information already available provides evidence on the type of code carried by ribonucleic acid. In what follows, only the 'non-overlapping' types of codes will be discussed.

The most obvious and reliable method of determining the nature of the code would be inspection of sufficiently long sequences of ribonucleic acid and the corresponding protein. The nearest approach to this is provided by the ribonucleic acid viruses, the ribonucleic acid of which apparently codes a single molecular species of protein⁵. As information is available on the approximate compositions of viral proteins and ribonucleic acids the problem is to determine what correlation exists between their compositions, and if such a correlation is found, to deduce the nature of the code. It is possible, of course, that a significant part of the ribonucleic acid has some other, non-coding, function, in which case its composition would bear no necessary relation to viral protein. Demonstration of a correlation would indicate the absence of such a fraction.

To correlate the change in ribonucleic acid associated with change in protein, it is first necessary to define a suitable quantitative measure of the amount of difference between two proteins or ribonucleic acids. This is the molar difference or change Δ_n which is defined as $\frac{1}{2} \sum |D_n|$, one half the sum of the absolute values of the differences between the quantities, expressed as moles per cent, of corresponding amino-acids in two proteins. The analogous molar difference for ribonucleic acid Δ_n is $\frac{1}{2} \sum |D_n|$. The reason for choosing these quantities is that they express how many mole fractions of residues in a protein (or ribonucleic acid) have to be replaced by others to obtain a second protein (or ribonucleic acid) of specified composition. Since the unit used is the mole fraction, valid estimates of compositional differences can be made even if the molecular weights are different.

The initial problem is to determine the 'coding ratio' n , or the number of nucleotides required to specify an amino-acid. Since the molar differences between ribonucleic acids or proteins are experimen-

tally determinable quantities, it is useful to consider what relation their ratio Δ_n/Δ_a , which will be referred to as r , bears to the coding ratio n . The nature of this relation can be seen from the following considerations.

Let each amino-acid be determined by n nucleotides. If a protein consists of k residues, the corresponding ribonucleic acid will have nk nucleotides. Each configuration of n nucleotides will then be the same mole fraction of ribonucleic acid as each amino-acid residue is of the protein. If a single amino-acid is replaced by another, the corresponding nucleotide configuration is also replaced, and the molar change in protein will then be the same as the molar change in ribonucleic acid, using nucleotide configurations as a unit. What can be observed, however, are variations in the quantities of individual nucleotides, and the observable molar change in ribonucleic acid will therefore depend on the compositions of the nucleotide configurations which replace each other. For example, a nucleotide configuration Ad-Ad-Ad* could be replaced by Gu-Gu-Gu. In such a case the molar change in ribonucleic acid will be the same as the molar change in protein, $r = 1$. If Ad-Ad-Ad is replaced by Ad-Ad-Gu, $r = 1/3$. A configuration Ad-Gu-Cy could also be replaced by Cy-Gu-Ad, in which case $r = 0$.

Therefore, if one considers a single amino-acid replacement, r can range from 0 to 1; but if the coding hypothesis is correct r cannot exceed 1, and can be 1 only if the amino-acids which replace each other are determined by configurations which have no nucleotides in common. Configurations which have this property will be referred to as 'nucleotide-exclusive' sets. (Examples of such sets would be triplets Ad-Ad-Ad, Gu-Gu-Gu, nucleotide exclusive with respect to Cy-Cy-Cy, Ur-Ur-Ur, or Ad-Ad-Gu with respect to Ur-Cy-Cy.)

The situation is modified if one considers a change in protein involving several different residues. In such a case, r could be 1 only if the configurations in a ribonucleic acid molecule as a group were a nucleotide-exclusive set with respect to the configurations replacing them in the second ribonucleic acid molecule. There is a maximum of four such configurations, so that if five or more amino-acids differ in the two proteins r must be less than 1. This is assuming, of course, that each amino-acid corresponds to a different nucleotide configuration. Usually a random set of configurations would tend to have an overall composition rather similar to most other random sets which would replace them, so that r would tend to be of the order of $1/n$ or less, the exact value depending on the compositions of the nucleotide configurations involved.

It is now possible to consider the experimental evidence, consisting of data on six ribonucleic acid viruses (Table 1). From the foregoing, it will be evident that maximal but not minimal values of r are of interest, and therefore proteins and ribonucleic acids of other viruses are compared to turnip yellow virus, the ribonucleic acid of which differs radically from the others. Molar differences for protein and ribonucleic acid are calculated on this basis.

The ratio of molar difference in ribonucleic acid to molar difference in protein, taking turnip yellow virus as a standard, has the following values: southern bean mosaic virus, 0.90; tomato bushy stunt virus, 0.75; cucumber virus, 0.66; tobacco mosaic virus, 0.83; and poliovirus 1.09. Two of these ratios, for southern bean mosaic virus and poliovirus, are close to 1, the maximum possible if the coding hypothesis

is correct. If $r = 1$ this implies that all amino-acids differing between two viruses are determined by configurations which are nucleotide-exclusive as between the two ribonucleic acids. Now as the molar difference between the ribonucleic acids of turnip yellow virus and poliovirus and southern bean mosaic virus is due entirely to a large excess of cytidylic acid in turnip yellow virus, and this excess is quantitatively about the same as the molar difference between the proteins, it follows that all, or virtually all, amino-acids which are more abundant in turnip yellow virus protein than in the proteins of southern bean mosaic virus and poliovirus must be determined exclusively by cytidylic acid. At least four amino-acids (isoleucine, lysine, proline and threonine) are significantly more abundant in turnip yellow virus than in either southern bean mosaic virus or poliovirus. It would thus appear that more than one amino-acid must be determined by configurations of nucleotides containing only cytidylic acid. This is an unexpected result as it suggests that the coding ratio may be 1, and that viral ribonucleic acid does not carry sufficient information to specify the viral protein completely.

Once a coding ratio of 1 is suggested, there is available a method, quite independent of any of the above arguments, for testing the validity of the proposal, the 'assignment test'. It should be possible to assign to each amino-acid a nucleotide in such a way that the composition of the corresponding ribonucleic acid can be calculated from the composition of the protein. This test is the more stringent as the number of ribonucleic acid-protein pairs increases. Failure to meet this test is, of course, a telling argument against the hypothesis.

The following assignments are suggested: Adenylic acid; glutamic acid, glutamine, glycine, leucine, phenylalanine and tryptophan. Cytidylic acid; cysteine, lysine, methionine, proline, and threonine. Uridylic acid; aspartic acid, asparagine, isoleucine, histidine, and serine. Guanylic acid; alanine, arginine,

tyrosine, and valine. The sum of amino-acids in each group is the predicted mole fraction of the corresponding nucleotide in the ribonucleic acid, shown in Table 1. In spite of the fact that the compositions of ribonucleic acid and protein of most viruses are only approximately known, concordance of the calculated and experimentally determined abundance of nucleotides in ribonucleic acid is good (Table 1). The Bravais-Pearson coefficient of correlation is 0.92 ($N = 24$), a very significant value. So far as the available evidence goes, the assignment test supports the hypothesis.

In assessing the validity of the proposed amino-acid-nucleotide assignments two sources of possible error should be considered. All the viruses in Table 1, other than turnip yellow virus, are of rather similar composition, and the objection can be raised that the correlation is merely between these viruses as a group and turnip yellow virus, effectively involving only two rather than six independent sets of determinations. That this is not the case, however, is shown by calculating the correlation coefficient without the data from turnip yellow virus, which is 0.87 ($N = 20$) still highly significant. Concordance of the predicted and determined ribonucleic acid composition is therefore still good within this group of similar viruses, although the range of variation is less.

A second, more serious, objection is that from the nature of the case the assignments of amino-acids to nucleotides are selected to give a good correlation, and that the concordance is therefore artificial. This objection is of course quite valid when only one or two cases are considered. But the probability that such a selection will be possible, when no real correlation exists, falls sharply as the number of cases increases. It is indeed a merit of the proposed hypothesis that it can be readily tested by refining analyses and applying them to viruses not yet investigated. So far only the composition of tobacco mosaic virus has been determined with the accuracy modern methods allow.

If the coding ratio of 1 is supported by further data it will be evident that viral ribonucleic acid does not carry all the information required to specify the corresponding protein, and the virus must be considered a joint product of both viral ribonucleic acid and the host. Nothing now known contradicts such a possibility.

Support from the National Science Foundation (U.S.A.) is gratefully acknowledged.

Note added in proof. A recent more extensive re-determination of the composition of poliovirus ribonucleic acid¹⁸ gave Ad, 0.285; Cy, 0.220; Gu, 0.240; Ur, 0.253, which is in much better agreement with the predicted ribonucleic acid composition than the earlier results quoted in Table 1. The coefficient of correlation between predicted and found ribonucleic acid composition for all viruses, using these new data, is 0.95.

HÆMOGLOBIN DIFFERENCES IN INBRED STRAINS OF MICE

By DR. HELEN M. RANNEY, DR. G. MARLOWE SMITH
and DR. SALOME GLUECKSOHN-WAELSCH

Department of Medicine, College of Physicians and Surgeons, Columbia University, and the
Department of Anatomy, Albert Einstein College of Medicine, New York City

THE existence of genetically determined differences in the electrophoretic patterns of hæmoglobin of inbred strains of mice has been reported previously^{1,2}. When filter paper^{1,3} or starch granules⁴ were used as supporting media for zone electrophoretic analyses in veronal buffer pH 8.6, two types of hæmoglobin pattern were seen: type 1, also called 'single', was a homogeneous single hæmoglobin, and type 2, also called 'diffuse', contained at least two components, an electrophoretically rapid one with mobility comparable to that of type 1, and a quantitatively smaller electrophoretically slower component. These hæmoglobin patterns appeared to be controlled by a pair of alleles, *Hb¹* and *Hb²*. Of eleven strains of mice tested, three showed the type 1 pattern only, five the type 2 pattern and three strains segregated for both. The hæmoglobin of mice of the *F₁* generation, from crosses of type 1 with type 2 resembled, on electrophoresis, the pigment of the type 2 parent. Recently hæmoglobin differences have been demonstrated in different inbred strains of mice with various electrophoretic methods, for example, starch granules⁵, starch gels⁴ and agar gels⁶.

That the relationship between hæmoglobin genes and hæmoglobin types in the mouse was perhaps more complex than assumed originally was suggested by the observation of five different hæmoglobin bands in the work of Rosa *et al.*⁴, who used starch-gel electrophoresis. For this reason two observations made in the course of our work on mouse hæmoglobin seemed to require further investigation:

(1) Aqueous solutions of carbonmonoxyhæmoglobin from mice of the *DBA* strain with hæmoglobin type 2 developed a precipitate on prolonged standing at 4° C. whereas no such precipitate developed in hæmoglobin solutions from mice of the *Kink* strain with hæmoglobin type 1.

(2) Different mice of the *DBA* strain with hæmoglobin type 2 as well as of the *F₁* generation from crosses of *DBA* × *Kink* (resembling hæmoglobin type 2) showed great variability in the amount of the electrophoretically slow component of the diffuse type 2 hæmoglobin.

The present work was an attempt to investigate further these two observations and their possible relationship to the presence of several hæmoglobin bands in certain mice as reported by Rosa *et al.*⁴.

Blood was obtained by cardiac puncture of anaesthetized mice, and hæmoglobin was prepared by the method of Drabkin⁶. Oxyhæmoglobin was prepared for solubility studies, and carbonmonoxyhæmoglobin was used for electrophoretic and ultracentrifugal analyses.

The appearance of a precipitate in stored hæmoglobin solutions from *DBA* and *F₁* mice and the absence of precipitation in stored *Kink* hæmoglobin suggested that the two hæmoglobins might differ in solubility. Therefore solubility studies were carried out using a modification of Itano's⁷ method. In 3.17 *M* phosphate buffer, and sodium hydrosulphite, *Kink* hæmoglobin was more soluble (Table 1) than *DBA* hæmoglobin; a value approximately intermediate between these two was obtained for *F₁* hæmoglobin.

Starch-gel electrophoresis of carbonmonoxyhæmoglobin was carried out on horizontal and vertical gels

Table 1 SOLUBILITY OF HÆMOGLOBIN OF INBRED MICE IN 3.17 *M* PHOSPHATE BUFFER, pH 7.2

Strain	Amount Hb added* O.D.	Amount Hb soluble O.D.
<i>DBA</i> /1	0.335	0.164
<i>Kink</i>	0.335	0.262

* These values were obtained by recording the optical density of the hæmoglobin in 2.5 molar phosphate buffer and hydrosulphite⁷; no precipitation occurred under these conditions

according to the methods of Smithies^{8,9}, within one week after bleeding the animals. This analysis of haemoglobin of Kink mice (type 1) revealed a single haemoglobin band. *DBA* (type 2) haemoglobin included the same and three additional bands, one faster than the main component and two faint slower components. These same three bands, as well as the 'single' band, were visible in F_1 (*DBA* $\times$ Kink) haemoglobin although the electrophoretically slow components were very faint. A semiquantitative method for measuring the relative amounts of haemoglobin components was based on dissolving a known volume of starch gel with its haemoglobin in concentrated hydrochloric acid, and the preparation of a blank of the same volume of starch gel in hydrochloric acid without haemoglobin. Concentrated acid was used, because the presence of excessive amounts of water was associated with turbidity of the resultant solutions. The optical densities of the hydrochloric acid-starch-gel solutions at 400 m μ were obtained on a Bausch and Lomb spectrophotometer. The average amount of slow components in 16 *DBA* animals was 20 per cent and in 40 F_1 animals 4 per cent of the haemoglobin; no slow component was detectable in Kink haemoglobin (Table 2). However, when *DBA* and F_1 specimens were stored at 4° C. as either carbonmonoxy- or oxy-haemoglobin, slow components became apparent in those F_1 specimens in which they were initially lacking, and increased in quantity in other F_1 and in all *DBA* specimens. Haemoglobin solutions of Kink (type 1) animals stored in identical circumstances failed to accumulate a slow component.

Table 2 ELECTROPHORETICALLY SLOW COMPONENTS OF HAEMOGLOBINS OF INBRED STRAINS OF MICE

Strain	No. of animals	Slow components % of total Hb	Main component % of total Hb
<i>DBA</i> /1	16	5 to 58 (av. 20)	80 (av.)
Kink	10	0	100
F_1	40	0 to 20 (av. 4)	96 (av.)

In order to study the effect of storage on the amount of electrophoretically slow component, pooled haemoglobin solutions were prepared separately from five *DBA*, from five F_1 , and from five Kink animals. Electrophoretic and ultracentrifugal analyses of the haemoglobin solutions were carried out three days after bleeding and repeated after 28 days of storage at 4° C. (Fig. 1).

Initial starch-gel electrophoresis of the different mouse haemoglobins gave the picture described before. When the electrophoretic analyses were repeated after 28 days, Kink haemoglobin appeared unchanged, whereas marked changes were noted in *DBA* and in F_1 (*DBA* $\times$ Kink) specimens. Electrophoresis of the *DBA* (type 2) specimen now revealed only two components: (1) the electrophoretically slowest band which had increased markedly in amount, and (2) the electrophoretically most rapid component. Electrophoresis of F_1 (*DBA* $\times$ Kink) haemoglobin after storage revealed changes similar to, but not identical with, those in the parent *DBA* (type 2) haemoglobin: the electrophoretically slowest component had increased markedly, and a rapid component comparable in electrophoretic migration to the rapidly migrating component of *DBA* haemoglobin was seen. However, in the stored F_1 haemoglobin, an electrophoretic component of the same mobility as that of haemoglobin of the Kink (type 1) parent was still evident.

The initial ultracentrifugal analyses revealed a single peak in Kink and F_1 haemoglobin in contrast to

Fig. 1. Electrophoretic and ultracentrifugal analyses of carbonmonoxyhaemoglobin of inbred strains of mice. A, Initial vertical starch-gel electrophoresis of Kink, F_1 , and *DBA* haemoglobins. E, electrophoretic analysis of the same solutions after 4 weeks of storage at 4° C. Electrophoretic analyses were carried out for 16 hr. in borate buffer, photographs taken without staining. B, C, D, initial sedimentation diagrams of Kink, F_1 , and *DBA* haemoglobins respectively. F, G, H, sedimentation diagrams of same solutions after 4 weeks of storage. Ultracentrifugal analyses were carried out at a concentration of 2 gm. per cent in a 3-mm. cell at 50,780 r.p.m. in a Spinco model E analytical ultracentrifuge. Photographs taken in mid-period of each run.

the *DBA*, which contained in addition a smaller more rapidly moving peak. On ultracentrifugal analysis after the four-week storage period, a small rapidly moving peak appeared in the pattern of the F_1 haemoglobin which now resembled the initial pattern observed in *DBA* samples, and the height of the rapidly moving peak of *DBA* haemoglobin increased markedly during this period.

The sedimentation constant for the main peak of mouse haemoglobin was $S_{20} = 4.2 \times 10^{-13}$, which is within the range of values given for other animal haemoglobins by Svødberg and Pedersen¹⁰.

A possible interpretation of the changes in the electrophoretic analysis of type 2 haemoglobin after a

storage period may be derived from the data of Smithies³, who showed that in starch gels the rate of electrophoretic migration is apparently dependent on size as well as on electrical charge of the proteins. Thus, the observations reported here may be due to the fact that part of the haemoglobin of *DBA* mice (type 2) may tend to aggregate in solution while that of Kink (type 1) does not. The increase in amount of an electrophoretically slow component in stored *DBA* and F_1 (*DBA* × Kink) haemoglobin solutions further suggests that the slow components may be the products of aggregation of haemoglobin molecules.

The results of ultracentrifugal analyses of *DBA* and of F_1 haemoglobin also provide evidence for aggregation of these haemoglobins during storage. In F_1 (*DBA* × Kink) haemoglobin, a rapidly sedimenting, heavy component appeared during the storage period, and, in *DBA* (type 2) haemoglobin, the heavy component present in the initial runs increased markedly in amount during the same 28-day period.

The faint electrophoretic bands of slowly migrating haemoglobin of the initial F_1 (*DBA* × Kink) specimens probably represented material quantitatively insufficient to be detected on ultracentrifugal analysis. However, after storage and at a time when the electrophoretically slow component of F_1 haemoglobin had increased in amount, a new component appeared in the sedimentation diagram of the ultracentrifugal analysis. Similarly during the storage period there was correlation between increase in amount of the electrophoretically slow component of the *DBA* (type 2) haemoglobin and that of the heavy component in the ultracentrifuge. The simultaneous changes in behaviour of these haemoglobins on electrophoretic and ultracentrifugal analyses suggest the identity of the electrophoretically slow component with the rapidly sedimenting component in the ultracentrifuge; we have designated this component 'aggregated haemoglobin'.

In order to demonstrate that aggregation is a property of *DBA* (type 2) haemoglobin but not of Kink (type 1) haemoglobin, Kink haemoglobin labelled with iron-59 was mixed with an equal amount of unlabelled *DBA* haemoglobin. The absence, after six weeks of storage, of a significant amount of radioactivity in the slow component suggests: (1) that aggregation is indeed a property of the *DBA* haemoglobin molecule and not of Kink haemoglobin, and (2) there is no component of the *DBA* haemolysate which facilitates aggregation of Kink haemoglobin.

Large variations in the amount of electrophoretically slow component of different specimens of *DBA* and F_1 (type 2) haemoglobin are recorded in Table 2. Since the amount of this 'aggregated haemoglobin' seems to increase with storage time, some of the variation may be explained on the basis of time differences. However, differences in amount of haemoglobin aggregation during storage may depend on other factors such as the haemoglobin concentration of the haemolysate. Whether this slow component exists in the circulating erythrocyte is uncertain: we have repeatedly failed to demonstrate the electrophoretically slowest component when starch gel electrophoresis of *DBA* haemoglobin was carried out within 2–3 hr. after the animals were killed. In these circumstances, only the three electrophoretically rapid components were observed in the *DBA* haemoglobin specimen. When electrophoretic analysis of *DBA* haemoglobin specimen was carried out after storage at 4° C. for several months, somewhat more aggregated haemoglobin appeared, but the rapid component

(Fig. 1) was still present. Further studies of factors affecting the rate of haemoglobin aggregation are under way in our laboratory.

The appearance of aggregated haemoglobin in the stored haemolysate of *DBA* and F_1 (*DBA* × Kink) mice may be related to the spontaneous denaturation of mouse haemoglobin observed by Rosa *et al.*⁴. The observations on aggregated haemoglobin in the present report were made on haemoglobin solutions in which no visible precipitation had occurred. On more prolonged storage, a haemoglobin precipitate appeared in the *DBA* and F_1 (*DBA* × Kink) haemolysates: both the supernatant haemoglobin solution and a solution of the precipitate in veronal buffer pH 8.6 were found to exhibit the characteristic spectroscopic absorption bands of carbonmonoxyhaemoglobin. After appropriate treatment of the solutions, the absorption bands of oxyhaemoglobin and of reduced haemoglobin were readily seen in both.

At least part of the differences between *DBA* (type 2) and F_1 (*DBA* × Kink) haemoglobin could be explained by the presence of Kink (type 1) haemoglobin in F_1 mice. The smaller amount of aggregated haemoglobin in stored F_1 (*DBA* × Kink) haemolysates may reflect the presence of a smaller amount of *DBA* haemoglobin in these animals than in the *DBA* parent. Whether this aggregation is a property of the haemoglobin of all mouse strains which were originally classified in the type 2 haemoglobin group is uncertain^{1,3}; the present work was confined to haemoglobin of *DBA* and Kink animals and their F_1 offspring.

Our own work^{1,3}, considered together with that of others^{2,4}, seems to indicate that the genetic control of mouse haemoglobin type may be fundamentally analogous to that described for human haemoglobins in that the phenomenon of co-dominance obtains. The two alleles, *Hb*¹ and *Hb*², each determine the presence of one particular type of haemoglobin, that is, 'single' or 'diffuse' and heterozygotes contain a mixture of these two electrophoretically separable haemoglobin types. The 'diffuse' haemoglobin type from *DBA* mice determined by the allele *Hb*² contains several components, at least one of which may undergo aggregation. The 'single' haemoglobin type from Kink mice used in this work, on the other hand, exhibits a homogeneity comparable to that of human haemoglobin A₁ when subjected to various electrophoretic conditions. Haemoglobin from F_1 ('single' × 'diffuse') mice representing a mixture of the parent haemoglobins differs from either parent type, both in quantity and quality of components. It is difficult to carry further the comparison of genetic control of mouse haemoglobins with that of human haemoglobins in the absence of further knowledge of the chemical differences between haemoglobins of type 1 and type 2.

This investigation was supported by Grants A 1017 and B 931 from the National Institutes of Health and by a grant-in-aid from the American Cancer Society.

ASTRONOMY

A New Correlation of the Mayan and Christian Calendars

BECAUSE solar and lunar eclipses and certain other lunar phenomena tend to repeat themselves in a periodic fashion, it has often been stated that it will be impossible to determine the correlation of the Mayan and Christian calendars from astronomical data alone. As a result, the two most generally accepted correlations, the Spinden¹ ($A = 489,384$) and the Goodman-Thompson² ($A = 584,283$) depend in part on historical records; A , the Ahau equation, is the Julian Day Number of the zero date of the Mayan calendar. This communication puts forward a correlation which rests on astronomical data and the assumption that the Spinden and Makemson³ ($A = 489,138$) correlations are within 100 years of the truth, an assumption suggested by early radio-carbon results.

This assumption and a new interpretation of certain pages of the Dresden Codex allow one to proceed to a determination of A with only slight ambiguity. I suggest that the second line on page 24 of the Dresden Codex indicates dates common to a Venus ephemeris and a solar eclipse table, and that the three lines of month names and numbers on pages 46-50 of the Codex, instead of providing three separate ephemerides for Venus, were designed to give dates of solar eclipses preceding and following particular solar eclipses associated with some special dates in the Venus ephemeris.

Let us assume (a) that the initial date of the Venus tables, 9-9-9-16-0, 1 Ahau 18 Kayab, as given on page 24 of the Dresden Codex, is also the date of a solar eclipse visible in Central America; (b) that the interval from this date to 9-14-2-6-0, 1 Ahau 18 Uo (page 47, Dresden Codex), 33,280 days (line 2, page 24, Dresden Codex), is an interval between two solar eclipse syzygies as well as the interval between two important Venus dates, namely, from a first appearance of Venus as a morning star to a somewhat later disappearance as an evening star; (c) that A lies between 489,384 - 36,524 and 489,384 + 36,525, which is equivalent to assuming that 9-9-9-16-0 lies between A.D. April 12, 263, and A.D. April 12, 463, both dates in the Gregorian Calendar. Assumption (c) is a re-statement of the one offered in the first paragraph above, namely, that the Spinden correlation is within a hundred years of the truth.

One can now examine the list of solar eclipses in Oppolzer's "Canon Der Finsternisse", looking between A.D. 263 and A.D. 464 for a solar eclipse which was visible in Central America, and which occurred very near a date at which Venus was in inferior conjunction with the Sun. In this interval, there were two solar eclipses meeting this description. The first was an annular eclipse on A.D. December 22, 344, G.C., the second a total eclipse on A.D. December 1, 392, G.C. Equating the former date with 9-9-9-16-0 yields an

Ahau equation, $A = 482,699$. The latter date gives $A = 500,210$.

In this brief communication, it does not seem wise to try to give all the reasons for discarding the second value of A ; rather it appears more desirable to present some of the reasons for adopting the first, namely, $A = 482,699$.

Consider now the three sets of numerals and month names in the lower part of pages 46-50 of the Dresden Codex. The three initial dates, or 'lubs', are 3 Xul, 18 Kayab, 13 Mac, reading from the bottom up. Let us now examine the six dates:

- I. 9-8-3-16-0, 1 Ahau 3 Xul
- II. 9-9-9-16-0, 1 Ahau 18 Kayab
- III. 9-11-3-2-0, 1 Ahau 13 Mac
- IV. 9-12-16-6-0, 1 Ahau 8 Chen
- V. 9-14-2-6-0, 1 Ahau 18 Uo
- VI. 9-15-15-10-0, 1 Ahau 18 Pax

Using $A = 482,699$, each represents a date within about one day of a solar eclipse syzygy. Venus was 4 days past and 1 day before inferior conjunction with the Sun at (II) and (V) respectively; 286 and 282 days past inferior conjunction and hence near superior conjunction at (III) and (VI); 13 and 14 days before inferior conjunction at (I) and (IV). The consecutive intervals between the dates as listed in order above are: 9,360; 11,960; 11,960; 9,360; and 11,960 days. The interval from (II) to (V) is 33,280 days, one of the numbers on line 2, page 24, of the Dresden Codex. All these intervals are close approximations to intervals between solar eclipse syzygies.

Let us next consider three of the dates given on page 52a of the Dresden Codex:

- VII. 9-16-4-10-8, 12 Lamat 1 Muan
- VIII. 9-16-4-11-3, 1 Akbal 16 Muan
- IX. 9-16-4-11-18, 3 Eznab 11 Pax

These dates have often been considered as important items in the interpretation of the lunar tables of the Dresden Codex. The Ahau equation, $A = 482,699$, makes these dates A.D. 477 September 23, October 8 and October 23, G.C. The first date is that of the autumnal equinox, and the third is a solar eclipse syzygy date. The second date is that of a full Moon, one month before a lunar eclipse.

Finally, among the 92 different dates given by Teeple⁴, if one omits Nos. 10, 85 and 94, the differences between the age of the Moon, as computed using modern tables (using $A = 482,699$) and as given by the Mayans (in the sense Computed-Mayan), all lie between +1.65 and -4.25. There is some evidence that solar eclipses visible in Central America were used to adjust lunar counts; in some cases, corrections of opposite sign were made about the same time in Copan and Piedras Negras, near the time of a solar eclipse visible in those cities.

I wish to acknowledge the generous assistance, particularly in the matter of reprints, of Dr. H. J. Spinden, Dr. M. W. Makemson and Mrs. Howard D.

Day, a niece of Prof. R. W. Willson. I have been fortunate in having an excellent group of students who have tackled the astronomical computing with enthusiasm.

ASTROPHYSICS

The Possibility of Detecting a Gravitational Red Shift in 21-cm Radiation from the Galaxy

THE interesting suggestion has recently been made by Landovitz and Marshall¹ that a gravitational red shift might be detectable in observations of the 21-cm. hydrogen line from the inner regions of the Galaxy. The effect is proportional to the difference in gravitational potential between the point of emission and the Earth's surface, and so could give independent information on the mass of the Galaxy. Currently accepted values for the mass and scale of the Galaxy would lead to a frequency shift of -3 kc./s. for radiation originating near the galactic centre; this corresponds to a Doppler velocity of $+0.7$ km./sec.

Landovitz and Marshall point out that this shift would have to be isolated from the much larger Doppler shifts (typically 50–100 km./sec.) arising from the differential rotation of the Galaxy, and suggest methods by which the separation might be made. There are, however, some other effects which appear to have been overlooked by Landovitz and Marshall, and these add considerably to the difficulty of picking out the gravitational effect.

The proposed tests involve a search for asymmetries in the velocity pattern of the 21-cm. radiation over the galactic plane. Rotational effects will be symmetrical about the direction to the galactic centre, but gravitational effects will not. I have recently been concerned with some closely related symmetry questions, through comparisons between our own 21-cm. survey of the southern part of the Milky Way strip² and the corresponding Leyden survey for the northern part³. Some degree of asymmetry does exist, and in consequence a simple rotation picture cannot give a satisfactory interpretation of the observational results. It seems probable, however, that the asymmetry is related to imperfectly understood motions, rather than to a gravitational shift.

A rotational velocity curve can be derived from 21-cm. observations by the method of Kwee, Muller and Westerhout⁴, which they applied to the Leyden data for the northern side of the Sun-centre line. An application of the same method to the southern data is found to give slightly lower velocities. (The reality of this difference between the two velocity curves has also been confirmed by other lines of approach.) The difference of velocity between the

southern and northern curves varies with galactic longitude in the way which would be produced by an additional motion of the Sun of about 7 km./sec. outwards from the galactic centre.

In all 21-cm. reductions to date, the observed velocities have been corrected to allow for the so-called 'standard' solar motion relative to the local centre of rest. This value for the solar motion has in effect been determined from the mean motion of stars within 2–3 kiloparsecs of the Sun, and the above result implies that the Sun and the local centre of rest are moving outwards at 7 km./sec. with respect to a larger galactic frame of reference.

Some other considerations suggest that the gas at the Sun's distance from the centre is also streaming outwards with about the same velocity. This motion is presumably connected with the large 'expansion' velocities which have been found in the nuclear region of the Galaxy⁵, with the inference that all the gas in the galactic disk is moving outwards, with a velocity which decreases with increase of distance from the centre.

These motions produce substantial asymmetries in the Doppler shifts on the two sides of the direction of the galactic centre, overshadowing the somewhat similar asymmetry which Landovitz and Marshall hoped to use to separate the gravitational and rotational effects. Admittedly, there will be second-order differences in the pattern of the various effects over the galactic disk, but these are likely to be hidden by the random motions and local irregularities.

We should of course consider the possibility that the observed asymmetry, which has been attributed to other causes, might in fact be a gravitational shift. For this to be so, the mass of the Galaxy would need to be increased by 10–20 times from the present estimates, and this seems very unlikely. Furthermore, the variation of the effect over the galactic plane is more in keeping with solar motion as a cause.

The test proposed by Landovitz and Marshall for recognizing the gravitational effect has the further difficulty that the integrated brightness in any direction is weighted heavily in favour of the nearby gas, where the effect is smaller still. One way to concentrate attention on the central region is to consider the small central disk and ring, which have recently been discovered by Rougoor and Oort⁶. These appear to be rotating at nearly 300 km./sec., and a 0.7 km./sec. asymmetry would be difficult to detect. The observed distribution pattern of the radiation in velocity and longitude does show a marked asymmetry, of rather complex form, but it seems more likely that structural factors are responsible for this.

So far we have only considered the potential variation in the galactic plane; but there is also a gradient of gravitational potential in a direction normal to the galactic disk. This would lead to a 'blue shift' in observations towards the galactic poles. A blue shift of a few kilometres per second is in fact observed over most of the high-latitude regions (ref. 7, and unpublished work by R. X. McGee), but it is about two orders of magnitude too large for the potential difference which would be expected over the few hundred parsecs where most of the gas is believed to be.

An observation of the gravitational red shift in our own or an external galaxy would be very valuable; but there seems to be little possibility of recognizing

it, until the detailed structure and motions have been established more definitely.

RADIOPHYSICS

Identification of Mode in Low-Frequency Sweep Ionospheric Sounding, and Interference Patterns between Overlapping Echoes

To help determine the origin of ionospheric echoes received on low-frequency sweep equipment it is very desirable to know their polarization, but unfortunately such information is not easy to record or display in a convenient manner. However, one of the most important parameters of the polarization is the sense of rotation of the wave vector, and a method has been developed which displays this in a simple way on a normal $h'f$ record.

A conventional pulse transmitter is used, operating over the swept range of 100 kc./s.—1,000 kc./s. The echo is received on a pair of crossed coplanar horizontal dipoles and analysed into its two circular components by means of a two-channel receiver with appropriate phase shifters¹ (see Fig. 1). The resulting video signals are electrically subtracted and applied to the grid of a conventional recording cathode-ray tube with its quiescent brightness adjusted to a level midway between zero and full intensity. Thus any particular echo, which will in general be elliptically polarized, will be displayed either as a light trace or dark trace, depending on its sense of rotation. A linearly polarized echo will not be displayed.

In the examples, a dark trace represents $N \rightarrow E$ (right-handed) polarization and a light trace $N \rightarrow W$

Fig. 2 0415 January 24, 1960

Fig. 3. 0615 March 26, 1960

(left-handed); Fig. 2 shows a record in which echoes of both polarizations are clearly visible. The form of this particular record is similar to that described by Watts² and the polarization is that which we would expect theoretically if the N_o -levels for all frequencies in the range are at heights greater than the v_o -level. (The terminology is that of Ratcliffe³.)

A particularly interesting effect sometimes observed is the appearance of interference fringes (see Fig. 3). These can be produced if either or both of two overlapping echoes have non-circular polarization, since interference can then take place in either interference fringe channel. Now the fringes are produced as the frequency varies, and hence are a representation of the rate of change (with frequency) of the difference in phase between the two echoes. But, as is well known, the rate of change of phase, ϕ , with frequency is just equal to the pulse delay of a system, so that in this case it should correspond to the time-interval between the reception of the two echoes. Or, in terms of group height, h' , we have:

$$(h'_1 - h'_2) = \frac{c}{2} \frac{\partial}{\partial \omega} (\phi_1 - \phi_2)$$

There are two possible reasons for the occurrence of a double trace:

(i) If the electron density increases monotonically with height and the gradient is not too great, then ray theory applies, and two magneto-ionic components will be reflected from the layer provided $v \ll v_o$ and $v \ll \omega$. In this case we expect the upper of the interfering echoes to have $N \rightarrow E$ polarization and the lower to have $N \rightarrow W$. This is just what is observed in Fig. 3. The separation of height of the echo computed from the observed fringe width agrees with that actually observed, namely, 12.5 km. and 12 kc./s.

(ii) If the electron density profile contains sharp gradients, partial reflections will occur and may give rise to split echoes. In this case, the polarization which the echoes will

Fig. 1. Equipment block diagram

have is not at all obvious, but we still have the possibility of production of interference fringe. Examples have been observed of interference fringes between echoes, which, because of their polarization, can only be explained by this mechanism.

It should be noted that whenever fringes are observed, their separation can be measured with precision, and this gives a much more accurate measure of the group-height separation of the echoes than could be obtained by direct measurement of a conventional h/f record. In fact, sometimes fringing can be observed when the existence of a split echo might not otherwise be evident, thus providing independent information about the fine structure of the E -region.

PHYSICS

Small-Angle Scattering of X-Rays from Deformed Natural Graphite

EXAMINATION of deformed metals using techniques of small-angle scattering of X-rays¹, stimulated by the development of theories and experiments on defects in crystals, has been made. Some results obtained along these lines with natural graphite are reported in this communication. In order to obtain deformed graphite it was treated either mechanically or chemically as follows:

(1) *Rolling*. 1 gm. of Ceylon graphite powder was pressed into a copper tube, 5 mm. external diameter and 3 mm. internal diameter, and sealed by turning down both ends. Afterwards the tube was pressed between plates to 4 mm. thick by rolling in a hand mill (5 cm. diameter). The thickness was reduced to 3.35 mm. after 4 passes through the first setting of the roller gap, and it was successively reduced to 2.8 mm., 2.4 mm., and 1.8 mm. by passing through, respectively, the second, third and fourth roller gap. The narrow solid strips of graphite obtained in this manner were carefully dispersed by lightly rubbing in boiling water.

(2) *Extruding*. Graphite powder was pressed into a cylinder, 4 mm. internal diameter, with a load of 200 kgm. The resulting solid graphite rod was introduced into a cylinder of the same diameter and extruded through a nozzle, 1 mm. or 1.5 mm. in diameter, at varying speed.

(3) *Pressing*. 50 mgm. of graphite powder was pressed each time with a piston in a cylinder of hard steel of 4 mm. internal diameter. The ultimate load applied was 3 tons.

(4) *Lamellar compounding*. Lamellar compounds with bromine² and potassium^{3,4} were prepared as usual since these compounds are reproducible and easy to prepare. It was debrominated at 100° C. in

Fig. 1. A, Normal Ceylon graphite; B, rolled graphite, first stage; C, second stage; D, third stage; E, fourth stage; F, extruded through 0.1-mm. nozzle; G, pressed at 16,000 atm.; H, pressed at 8,000 atm.; I, residue of brominated graphite; J, residue of potassium compound

air and at 650° C. *in vacuo*. Potassium was driven off at 400° C. in a sealed glass tube for 12 hr. Then the residue was transferred to a porcelain boat and heated at 800° C. for 1 hr. in an evacuated furnace. Use was made of a slit collimated camera having the sample to the photographic film distance of 28 cm. The determination of the scattering from the different samples was achieved by exposure, under constant operating conditions, on the same photographic film by means of the rotation of the film holder. The sample (100 mgm.) was situated immediately behind the collimating slit uniformly pressed in a holder 2×24 mm.² and while irradiating oscillated longitudinally with an amplitude of 14 mm. The crystallites in the holder were preferentially oriented so that the layer planes were at right angles to the X-ray beam. Cobalt radiation filtered through Ross-type filters was used.

The representative scattering curves are plotted in Fig. 1. The intensities of scattering increase with the degree of rolling from curves A to E. The degree of deformation of the graphite crystal may be expressed with Franklin's p -value⁵ and estimated as in my previous work⁶ to be, respectively, 0.05, 0.05, 0.055, 0.057 and 0.074. Besides this a slight progressive decrease of the grain-size L was observed and estimated to be, respectively, 827, 804, 741, 647 and 473 Å. from the half-peak width of the 0008 line and using nickel K radiation. For extruded graphite (F) the values are $p = 0.055$ and $L = 714$ and for pressed graphite (G) $p = 0.053$, $L = 755$. In the case of graphites treated mechanically the intensities of scattering were correlated with the p and L values. Abnormally small intensity (J) was obtained in the case of the sample treated with potassium, whereas p and L values were normal. The result was confirmed with the samples prepared under slightly different conditions. However, with the rolled samples treated and untreated with potassium, identical intensities of small-angle scattering were observed.

It will be apparent from Fig. 1 that the curves obtained are very nearly linear over the range of angles observed and approximately parallel to each other. From this the angle dependence of the

scattered intensity has been found to be $(2\theta)^{-2.5}$, which would correspond to $(2\theta)^{-2.5}$ in the case of pinhole collimated camera. $(2\theta)^{-2.5}$ dependence was observed by Grosskreutz and Rollins⁷ with stressed copper and aluminium in the same range of angles.

Townsend Ionization Constants in *n*-Alkanes

We recently measured the first Townsend ionization coefficient, α , in a series of *n*-alkyl chloride gases¹, and found that the dependence of α on molecular structure in these gases was similar to, but different in detail from, that indirectly inferred in the hydrocarbon gases by Devins and Crowe² and Heylen and Lewis³ from measurements of sparking potentials. In order to determine whether these differences are real or are the result of errors in analysis of the results for sparking potentials, we have undertaken the direct measurement of the first Townsend ionization coefficients in the *n*-alkane gases containing 1-6 carbon atoms.

Crowe, Bragg and Devins⁴ have, on theoretical grounds, related the ionization coefficient, α , to pressure, p , field, E , and to molecular structure through the relationships:

$$\frac{\alpha}{p} = \frac{A f(E/p) \exp(-BP/E)}{B = k\theta \epsilon_1^{3/2}} \quad (1)$$

A is a constant for a given gas, ϵ_1 is the ionization potential, θ the Ramsauer cross-section, and k , while not necessarily a constant for different gases, was found from measurements of sparking potential to be so for the hydrocarbon gases². The pre-exponential factor $f(E/p)$ in equation (1) was assumed to be equal to E/p for the hydrocarbons², although the range of E/p covered with the measurements of sparking potentials was insufficient to distinguish between $f = E/p$ and $f = 1$. Our measurements for the alkyl chlorides¹ showed that equation (1) gave a much better fit for those results if $f = 1$.

The experimental apparatus and procedure have already been described¹. The gases were more than 99 per cent pure. Pressures were varied from 0.5 to

Fig. 1. Dependence of α/p on B/p for the *n*-alkanes: $\circ$, methane; $\bullet$, ethane; $\square$, propane; $\blacksquare$, butane; $\triangle$, pentane; $\blacktriangle$, hexane; ∇ , α/E for butane.

20 mm. mercury and electrode spacings from 0.2 to 3 cm.

In Fig. 1 we have plotted our experimentally determined ionization coefficients for the *n*-alkanes containing 1-6 carbon atoms. The abscissa was chosen to separate the individual curves; values of B were obtained from individual plots of $\log \alpha/p$ against P/E and are listed in column 3 of Table 1. The curves all show linear regions over a variation in α/p of approximately fifty-fold, with some curvature below $BP/E = 1$ and above $BP/E = 5$. Such deviations are to be expected according to the theory⁴. If $f = E/p$ in equation (1), then the logarithm of α/E should be a linear function of P/E . In Fig. 1 such a plot is shown for butane, arbitrary units being chosen for convenience in plotting. The pronounced curvature suggests that, for the alkanes, as for the alkyl chlorides, equation (1) describes the results better if f is chosen to be unity.

Values of B for the alkanes were re-calculated from sparking potential data², assuming $f = 1$ in equation (1). The values, shown in column 4 of Table 1, are 10-25 per cent lower than those obtained in the present work.

Table 1. IONIZATION CONSTANTS IN *n*-ALKANES

Gas	A (cm ⁻¹ mm. Hg ⁻¹)	(a) $B(a)$ (V. cm ⁻¹ mm. Hg ⁻¹)	(b) $B(V_s)$ (V. cm ⁻¹ mm. Hg ⁻¹)	(c) $B(V_s)$ (V. cm ⁻¹ mm. Hg ⁻¹)	(d) ϵ_1 (eV.)	$\frac{B(a)}{\epsilon_1^{3/2}}$ (V. cm ⁻¹ mm. Hg ⁻¹ eV. ^{3/2})

a, This work; b, heavy illumination (ref. 2); c, light illumination (ref. 6); d, ref. 2.

Fig. 2. Relationship between $B/\epsilon_1^{1/2}$ and the number of hydrogen atoms for the normal alkanes, O, and the normal alkyl chlorides, □

An essential feature of the Townsend mechanism is the independence of the sparking potential on the level of cathode illumination, provided that adequate time is allowed for breakdown to occur. As Heylen and Lewis³ point out, however, for hydrocarbons, decreases in sparking potential of 10–20 per cent are readily observable on relatively moderate ultraviolet illumination of the cathode. Although with low levels of illumination they observed the same values of B for the alkanes as did Devins and Crowe², their values for the alkanes were distinctly lower². In Table 1, column 5, we have included earlier measurements of B of Devins and Crowe² made with a 'Pyrex' cell irradiated with a BH4 lamp. The effective level of illumination was therefore much lower than in their later work. These values of B agree much more closely with those obtained from measurements of α than do those obtained using a more heavily illuminated gap.

Utilizing our measurements of α , we can calculate from measurements of sparking potentials values for the second Townsend coefficient, γ , assuming the Townsend sparking criterion to be valid. For the relatively heavily illuminated gaps², values of γ increase approximately exponentially with decreasing E/p , and lie in the range of 10^{-2} – 10^{-6} . With the lightly illuminated gaps of Heylen and Lewis³ and of Devins and Crowe², values of γ are more nearly independent of E/p and much lower (10^{-8} – 10^{-9}). These results are consistent with the hypothesis of Heylen and Lewis³, which suggests that if γ is very low for the hydrocarbons, appreciable distortion of the field by space charge may occur below the Townsend threshold, even with moderate illumination.

Measurements of sparking potentials² had indicated that the cross-section θ was a colligative function of the number and types of atoms in a molecule if the contribution of the singly bonded carbon atoms is zero. In Fig. 2 we plot $B/\epsilon_1^{1/2}$, obtained from our direct measurements of α for the n -alkanes and n -alkyl chlorides¹, versus the number of hydrogen atoms. The least-square lines are: for the n -alkane gases, slope = 1.03 ± 0.05 , intercept = -0.1 ± 0.14 ; for the n -alkyl chloride gases¹, slope = 1.16 ± 0.03 , intercept = 2.97 ± 0.07 . The zero intercept for the n -alkane curve indicates a zero contribution to θ

from the carbon atoms, as was reported earlier², and the 12 per cent difference in slope suggests either a slightly different contribution of the hydrogen atom or different values of k for the n -alkane and n -alkyl chloride series.

The constant A for the n -alkane gases appears to be proportional to the number of hydrogen atoms per molecule. An understanding of the dependence of A on molecular structure must await further theoretical work.

Tungsten-185 in Precipitation and the Seasonal Variations in Fall-out

THE introduction of tungsten during the U.S. 'Hardtack' nuclear test series in 1958 provided a unique opportunity of identifying nuclear debris of known origin. From June 1958 until August 1959, tungsten-185 (half-life, 74 days), the tungsten isotope of most interest, was detected in precipitation occurring at Westwood, New Jersey and other stations¹. Data on both tungsten-185 and strontium-90, and other short-lived isotopes such as barium-140 and strontium-89, in rain-water cast light on the mechanism of stratospheric fall-out, and if suitable corrections for radioactive decay of the short-lived isotopes are made the fraction of debris from 'Hardtack' tests may be estimated. An initial activity ratio tungsten-185/strontium-90 of 500 on July 15, 1958, as suggested by Lockhart *et al.*², has been used in this work.

The deposition of tungsten-185 and strontium-90 in precipitation at Westwood, New Jersey, is shown in Fig. 1 together with the rainfall amounts. These curves were constructed by adding the activities in each rain within overlapping 30-day periods, each interval being advanced in 10-day steps. All tungsten-185 results were corrected for radioactive decay to August 15, 1958. Fig. 2 shows a similar graph

Fig. 1. Levels of tungsten-185 and strontium-90 deposition in precipitation at Westwood, New Jersey, during the period June 1958–July 1959

Fig. 2. Variations of the specific activities of tungsten-185 and strontium-90 in precipitation at Westwood, New Jersey

of the variation in specific activity of strontium-90 and tungsten-185 in rains for the period June 1958–July 1959.

It is clear that the deposition of these nuclides varies considerably during the period chosen for discussion. Furthermore, these variations are not due to differences in rainfall amounts as can be seen from the precipitation data in Fig. 1 and the specific activity results in Fig. 2. Perhaps two major peaks in tungsten deposition can be seen, one in November–December 1958, and a second in the spring of 1959. The latter is accompanied by a similar increase in deposition and specific activity of strontium-90, but with the former peak the increased strontium-90 deposition is not so pronounced. The abrupt rises in tungsten-185 and strontium-90 specific activities, commencing in early 1959 and attaining their peaks in mid-April, provide good evidence for the seasonal variation in fall-out first observed by Stewart *et al.*³ However, the tungsten curve supports the theory that this spring rise in fall-out is not wholly attributable to the Soviet testing schedule, as postulated by Martell⁴, but is rather a meteorological phenomenon and is independent of the geographical origin of the debris^{5,6}. The continuous deposition of tungsten-185 during the late autumn of 1958, two to three months after the last

major 'Hardtack' tests, is unlikely to be tropospheric debris and we must therefore attribute it to delayed stratospheric fall-out.

Fig. 3 shows the change in the tungsten-185/strontium-90 ratio with time. During early 1959 this ratio remained relatively constant over a six-month period. This indicates that the 'Hardtack' and other debris in precipitation were quite well mixed, and calculations, using the tungsten-185 results to obtain the accompanying 'Hardtack' strontium-90, reveal that only about 8 per cent of the strontium-90 was 'Hardtack' in origin. During earlier periods, that is, in late 1958, this contribution rose as high as 20 per cent. These findings are in good agreement with the conclusions of Lockhart *et al.*² from ground-level air measurements. Considerable changes in the tungsten-185/strontium-90 ratio occurred, however, during 1958, probably due to the Soviet testing at that time. Other isotope data (for example, strontium-89/strontium-90 ratios) obtained at this laboratory⁷ indicate that 70–80 per cent of the debris sampled during spring 1959 could be attributed to Soviet tests in the autumn of 1958.

The tungsten-185 data have demonstrated, therefore, that material injected into the stratosphere in the equatorial regions is involved in the seasonal variations of fall-out. The spring peaks in fall-out are therefore not entirely a result of the testing schedule nor are they entirely related to the area where detonations have occurred. Furthermore, it appears that the 'residence times' of material injected into the equatorial stratosphere can be relatively short, as discussed recently by Feely⁸.

Elimination of a Glow Discharge in an Induction-heated Vacuum Furnace

WHEN metals and other conductors are heated by induction at low gas pressures, difficulty is sometimes experienced due to electrical breakdown of the gas by the high-frequency electromagnetic field of the induction coil. The effect is most pronounced in the pressure-range, 0.01–0.5 mm. mercury¹. Occasionally the discharge becomes so intense that effective heating by the work-coil can no longer be obtained, particularly if high temperatures are required.

There has been little reported in the literature on the quenching of high-frequency discharges. McDonald *et al.*² found that by using traps cooled in liquid nitrogen to remove mercury vapour, the

discharge could be eliminated. Tokube *et al.*³ also found this to be effective. Bach *et al.*⁴ used a step-down transformer to reduce the voltage across the work-coil from 1,000 V. to 100 V. and found that this entirely eliminated the discharge.

The problem of eliminating such discharges was encountered in this Laboratory in the application of the isotope dilution method to the determination of gases in metals⁵. The technique involved the heating of a graphite crucible approximately 1 in. in diameter by 1 in. in length suspended by platinum wires in a vertical cooled tube 2 in. in diameter, in an atmosphere of carbon monoxide in the pressure-range 0.05–0.5 mm. mercury. Work coils 3 in. in diameter, with 5–10 turns of $\frac{1}{4}$ -in. copper tubing, were used in conjunction with an electronic generator of maximum output of 10 kV. amp. at a nominal frequency of 350 kc./sec. In earlier work⁵ in which a 2.5-kV. amp. generator was used and for which better coupling between coil and crucible was obtained, only a faint discharge was occasionally encountered.

In view of the scarcity of data, an outline of several approaches to the problem which have been made in this Laboratory may be of help to present and future users of induction-heated vacuum furnaces.

(a) *Gas pressure.* As a result of limitations on the weights of steel samples which can be used in this apparatus, the partial pressure of C¹⁸O and C¹⁶O is restricted to 0.05–0.5 mm. mercury. An attempt was made to quench the discharge by increasing the total pressure by adding an inert gas. Argon (I. potential 15.7 V.) and helium (I. potential 24.46 V.) were used at pressures up to 20–30 mm. mercury. In both cases an improvement was obtained at low power output; but at the power output which would be used during an isotope dilution run a strong discharge was still obtained.

(b) *Mercury Vapour Traps.* The furnace was isolated from any mercury vapour in the system by the use of solid carbon dioxide–acetone traps. Unlike other workers, McDonald and Tokube (*loc. cit.*), I did not find that this was significantly effective in quenching the discharge.

(c) *Use of Short Generator-Coil Leads.* The initial experiments were performed with the generator remote from the coil. Because of the possibility of poor grounding due to the long leads, the generator was placed as close as possible to the work coil. A massive earth connexion was also made between the generator and work coil. This assembly gave much better coupling and removed the discharge at low currents. However, it had no significant effect on the discharge at higher power output.

(d) *Grounding.* It was observed that there was a certain amount of grounding of the discharge through the clamps supporting the furnace. This produced dark spots on the glassware at these points, probably due to deposition of carbon and platinum particles carried by the ionized gas from the graphite crucible and supporting wires. Following this observation, attempts were made to ground the discharge by grounded wires dipping into the furnace cooling water, without any success.

(e) *Use of a Metallic Film.* During the course of the grounding experiments, it was discovered that the discharge was reduced most effectively by hanging unconnected copper wires in the furnace cooling water. The discharge was progressively decreased by increasing the number of wires. Thomson⁶ has suggested that the rapidly oscillating electric field is required to initiate a high-frequency discharge and

this was confirmed by later workers⁷. It seems likely, therefore, that the successful use of free-hanging wires to quench the discharge may be due to a shielding of the electric field, so that the field strength is reduced below that necessary to produce electrons, by being spread over a greater area of the furnace tube.

The effect of increasing the conductivity of the cooling water was then examined, since from the above argument this should also eliminate or decrease the discharge. It was found that very low concentrations ($<10^{-3}$ M) of strong electrolytes, such as sodium chloride, hydrochloric acid, or nitric acid, completely eliminated the discharge. Large pieces of very insoluble substances suspended in the cooling water (calcium fluoride, barium sulphate, silver chloride) had no effect on the discharge.

The final solution to the problem has been obtained by silver-plating, in strips, the inner wall of the furnace water-cooling jacket. When this has been done, no discharge is observed, even at maximum power output from the generator.

In conclusion I would like to acknowledge my thanks to members of the High-Temperature Group of this Laboratory and to Prof. A. D. McDonald of Dalhousie University for helpful discussion of this problem.

CRYSTALLOGRAPHY

A New Case of Crystallographic Stacking Fault: $U_3O_8 - \alpha$

By the use of modern electron optical techniques, the study of structures involving periodic stacking faults (or 'out-of-steps' between 'anti-phase domains') is making remarkable advances. Some of the most recent reports are referred to refs. 1–5. However, many contributions to this field have hitherto been confined mainly to physically ordered states of binary alloys. Now, in the course of electron diffraction investigation of uranium compounds, I have encountered a new case of fault structure which is connected with a chemical decomposition.

In Fig. 1 the electron diffraction pattern of a single crystal of orthorhombic uranium oxide (U_3O_8) is reproduced. The sample is very thin along [001], and the incident beam is in this direction. The pattern is compatible with the crystal structure of orthorhombic U_3O_8 proposed by Andresen⁶, and Chodura and Malý⁷. Since the uranium ions in the crystal are all arranged on (001) in a nearly hexagonal manner^{6,7}, the pattern exhibits a hexagonal feature as a whole. Moreover, the crystal consists presumably of inevitable twins, oriented at 60° to each other around the c-axis.

Fig. 1. Electron diffraction pattern of a single crystal of U_3O_8 .

Fig. 2. Electron diffraction pattern of the sample of Fig. 1 after being heated in vacuo.

When such a single crystal of U_3O_8 is heated *in situ* in the electron optical apparatus, it is reduced eventually to uranium dioxide (fluorite-type cubic) in a special orientation. However, prior to the appearance of the uranium dioxide phase the comparatively weaker spots of Fig. 1 suffer an anomalous splitting as shown in Fig. 2. The splitting becomes more pronounced as the reduction proceeds, while the comparatively stronger spots of Fig. 1 remain almost unchanged. Thus, it seems that before conversion of the orthorhombic lattice of U_3O_8 to the cubic lattice of UO_2 , the former undergoes a modification. The chemical formula for the modified stages should be U_3O_{8-x} , where x is a small positive variable.

In Fig. 3a the line-up of U^{6+} - and U^{5+} -planes in orthorhombic U_3O_8 with respect to the b -direction is depicted schematically. It is to be noted that actually the U^{6+} -planes trisect only approximately the spacing between adjacent U^{5+} -planes. Now, suppose that a particular mode of valency conversions of uranium ions (U^{6+} to U^{5+} or U^{4+} , and U^{5+} to U^{4+}) takes place so as to lead to the sequence, for example, of Fig. 3b. Suppose, moreover, that the spacings between adjacent U^{6+} -planes in Fig. 3b be either 1 or $4/3$ (taking the spacing in Fig. 3a as the unit), owing to slight changes in position of uranium ions accompanying the valency conversions. This is an out-of-step structure, where stacking fault takes place at every M -th step of the U^{6+} -plane. For Fig. 3b M is 3. It will be readily understood that M decreases as the reduction proceeds, since smaller M

means lower density of the U^{6+} -plane in the crystal (Fig. 3c and d). The asymmetric splitting of spots in the direction above-below in the patterns, such as Fig. 2, can be accounted for by such stacking fault structures, the amount of splitting depending on the value of M . That the split spots in Fig. 2 show an elongation is presumably due to the fact that the M values in the crystal fluctuate considerably around a predominant value. By introducing to the above a triad operation, corresponding to the presence of the 60° twinning, all the anomalous spots of Fig. 2 can be accounted for. The reduction of U_3O_8 to U_3O_{8-x} in this way is supposed to proceed until M decreases to unity (Fig. 3d).

A detailed account of this work will be given elsewhere.

MINERALOGY

Formation of Hydrogarnet by Chemical Reaction among Calcium Carbonate, Ammonium Chloride and some Silicates

THE Lawrence Smith method, which is well known as a procedure for the chemical analysis of alkali ions, has not been considered in the light of structural chemistry. Here we are considering the chemical reaction from the structural chemistry point of view and show that hydrogarnet is frequently formed, which suggests that the reaction should await further studies in relation to the natural skarnization.

As starting materials, we used specimens of feldspars (orthoclase, adularia, microcline, and sanidine) which are free from impurities other than feldspars. The known mixture of $KAlSi_3O_8/CaCO_3/NH_4Cl$ in the ratio (by weight) of 2 : 3 : 2 was heated at the temperatures $100^\circ C.$, $200^\circ C.$. . . $800^\circ C.$ for 1 hr., immediately cooled, and then washed about ten times with hot water to remove water-soluble salts. The residue was dried at room temperature and analysed by X-ray (Table 1) and chemically (Table 2).

Feldspar and calcite structures are persistent up to nearly $600^\circ C.$ Wollastonite structure begins to be formed from about $500^\circ C.$, and garnet structure begins to be formed from about $700^\circ C.$ The spacing of this garnet structure deviates slightly from that of grossularite. Owing to this fact, coupled with a considerable amount of ignition loss as revealed in the

Fig. 3. Successive stages of line-up of U -planes in the reduction of U_3O_8 to U_3O_{8-x} . Solid lines indicate U^{6+} -planes, and broken lines U^{5+} (or U^{4+}) planes. (a) corresponds to U_3O_8 (Fig. 1). The M values are ∞ , 3, 2 and 1 from left to right.

2.481	9	W			

W, wollastonite; G, reflexions corresponding to those of grossularite. Numerals in brackets mean indices of reflexions.

Table 2. CHEMICAL COMPOSITION OF THE RESIDUE OBTAINED FROM SANIDINE HEATED AT 650° C.

	Per cent
Silica	35.30
Alumina	12.33
Calcium oxide	43.27
Ignition loss (> 105° C.)	7.20
Water (-)	1.23
Total	99.33

chemical composition, it can be anticipated the garnet may belong to hydrogrossularite.

Earlier papers¹ indicated that the a_0 -parameter gradually increases through increasing amount of hydrogen replacing silicon in the grossularite-hydrogrossularite series.

In the present case, the spacing of the garnet structure has nearly a fixed value even in the specimen not having been with hot water. Hence, it can be considered that the hydrogrossularite structure has been formed in the chemical reaction and has nearly a fixed chemical composition. The a_0 -parameter was obtained as 11.9 Å., which is near to that of plazolite:

From the above data, the chemical compositions can be represented as:

and the amount of wollastonite obtained from this formula was about 47 per cent, which agrees with that obtained in the natural standard wollastonite specimen.

Heating the known mixture of leuchtenbergite/calcium carbonate/ammonium chloride in weight ratio of 1:1:1, we were able to obtain periclase and hydrogrossularite structures. Leuchtenbergite and calcite are persistent up to about 700° C., and periclase and garnet structures begin to be formed at about 600° C. The a_0 -parameter was obtained as 12.10 Å.

Table 3. CHEMICAL COMPOSITION OF THE RESIDUE OBTAINED FROM LEUCHTENBERGITE HEATED AT 800° C.

	Per cent
Silica	24.37
Alumina	17.32
Titanium dioxide	0.05
Ferrio oxide	0.48
Ferrous oxide	0.24
Magnesium oxide	21.66
Calcium oxide	29.22
Sodium monoxide	0.35
Potassium monoxide	0.19
Water (+)	5.77
Water (-)	0.13
Phosphorus pentoxide	0.16
Manganous oxide	0.06
Total	100.50

The chemical composition (Table 3) can be represented by the following formula:

These results may indicate that hydrogarnet can be formed even in a normal atmosphere at about 700° C. or above it, and ammonium chloride may play an important part in its formation. Probably, chlorine acts on calcium ions forming calcium chloride, which reacts on silicates, exchanging potassium ions with calcium ions, and the residue transformed into the following materials as wollastonite, garnet, and periclase. Hydrogen released from ammonium chloride may play an important part in the formation of grossularite.

RADIATION CHEMISTRY

Reactions of Nitric Oxide or of Oxygen with Benzene Selectively Excited to the Triplet State

We have recently described¹ a method of studying the reactivity of aromatic molecules in their lowest triplet states. For example, the system benzene + nitric oxide, irradiated within the paramagnetically induced² forbidden $T \leftarrow S_0$ band (2900–3400 Å.), reacts, the photochemically active radiation being absorbed neither by nitric oxide nor by benzene alone. The effect is considered as the reaction of nitric oxide in its ground-state.

The products of reaction were removed from benzene solution by extraction with 0.1 M aqueous sodium hydroxide and identified by chromatopolarographic separation³, examination of absorption spectra and polarographic curves, as *o*-nitrophenol and 2,4-dinitrophenol. Hence our previous assumption¹ about the formation of an isonitroso compound was not confirmed. Using the ferrioxalate actinometer⁴, we have measured the quantum yield of formation of 2,4-dinitrophenol in monochromatic light of $\lambda = 3130$ Å., finding $\Phi \approx 0.012$. *o*-Nitrophenol is formed simultaneously with comparable efficiency.

The influence of nitric oxide on ultra-violet absorption of benzene is similar to that of oxygen, both being due to paramagnetic properties of nitric oxide or oxygen molecules. It seemed very probable, therefore, that this analogy would also exist in the case of chemical reaction with benzene excited to the triplet state. Pure dried benzene was saturated with oxygen under a pressure of 100 atm. to favour the reaction. The samples were irradiated with ultra-violet light of spectral range 2900–3600 Å., or with the isolated mercury line 3130 Å. In both cases the reaction took place. We examined the absorption spectra of products extracted in water or 0.01 M sodium hydroxide solution. The absorption maximum observed in alkaline solution at

285 m μ is similar to that of the phenolate anion. This spectrum reveals also the existence of a second product, probably *o*-benzoquinone. This assumption is supported by the absorption spectrum of neutral aqueous solutions in which a distinct maximum at 277 m μ was observed and by a weak positive reaction with 2,4-dinitrophenylhydrazine. The quantum yield of formation of phenol determined with the ferrioxalate actinometer is $\Phi \approx 0.03$. The small values of the quantum yields of both reactions may be ascribed to the low stability of the primary addition products.

Recently, Loeff and Stein⁵ irradiated benzene in aqueous buffered solutions and identified phenol and muconaldehyde as reaction products. They assumed the addition of the hydroxyl radical to the unexcited benzene molecule; alternatively they mentioned the possibility of reaction of the oxygen molecule with an excited hydrocarbon molecule. However, they gave no further details.

In our experiments, the reaction investigated seems to be unambiguously that of benzene excited to the bi-radical triplet state with an oxygen molecule in the ground-state.

Examination of γ -irradiated Benzene for Optical Activity

In a recent communication, Starodubtsev, Gurskiy and Sizykh¹ studied optical effects in benzene resulting from its irradiation with γ -rays from a cobalt-60 source with a flux of 3×10^8 r./hr. They report in one short paragraph, which is here directly translated: "Interesting is the fact of rotation of the plane of polarization. Although the rotation is not large (0.7–0.9° at a dosage of 10^7 r. and sample thickness of 10 cm.) it nevertheless indicates the occurrence of asymmetric molecules not possessing a centre or a plane of symmetry".

This observation is potentially of great theoretical significance in that it suggests asymmetric synthesis from a symmetrical chemical reagent and, presumably, symmetrical photons. This could have a bearing on the origin of life as we know it, which is based on asymmetric molecules, and in many other fields. However, since the quoted report runs counter to currently accepted concepts of asymmetric induction and related reaction mechanisms, it was considered important to check the validity and reproducibility of the phenomenon.

For this purpose, specially purified benzene was prepared by taking reagent-grade thiophene-free benzene and subjecting it first to extraction with concentrated sulphuric acid until the washings were colourless, then washing with aqueous sodium carbonate and water, drying over potassium carbonate, fractional distillation from sodium and retaining the middle third cut, two fractional crystal-

lizations and, finally, redistillation from potassium. This product, boiled sharply at 80.5° (uncorr.) at 748 mm., n_D^{25} 1.4981, n_D^{20} 1.5009 ± 0.0001 (compared to n_D^{20} 1.5011 ± 0.0001 reported by Starodubtsev *et al.*¹). In a polarimeter cell of 40 cm. path length the observed rotation was $0.000^\circ \pm 0.002^\circ$ at 25° for the sodium-D line as read on a Rudolph Hi-Precision model 80 polarimeter.

The purified benzene was carefully degassed by alternate freeze-pump-melt cycles and trap-to-trap distillation on a vacuum line. Approximately 30 ml. were distilled into a cylindrical 'Pyrex' ampoule 21 cm. $\times$ 2.5 cm. diameter fitted with a break-seal. The sample was sealed under vacuum and irradiated in a 20,000-c. cobalt-60 source of conventional design² at a dose-rate of 6.0×10^7 ergs/gm. (c.)/hr.

After irradiation to an integrated dose of 3.3×10^7 r., the sample was removed from the source and again sealed to a vacuum system. The ampoule was opened under vacuum, and an atmosphere of dry helium was admitted to the system. The sample was then opened to the atmosphere and transferred quickly to the proper cells, previously flushed with helium, for examination.

The benzene solution was light yellow in colour and had an unusual not easily describable pungent odour which obscured that of the benzene. In attempts to analyse the solution on a Burrell Kromo-tog gas chromatograph employing an 8-ft. column packed with 'Apiezon L' on firebrick, the benzene came off well but the odorous component was retained and could not be removed from the column at room temperature or even at 100°.

The solution after irradiation had a refractive index n_D^{25} 1.4980 ± 0.0001 . An ultra-violet absorption difference spectrum was obtained on a Cary model 11MS double-beam spectrophotometer with the original purified benzene as the reference solvent. In a 1-cm. cell only four peaks were observed at wave-lengths between the solvent cut-off at 2800 Å. and the instrument limit at 8000 Å. These local maxima and their absorbances (in parentheses) as determined by appropriate dilutions were as follows: 4459 Å. (0.27), 4137 Å. (0.79), 3680 Å. (2.5) and 2767 Å. (38.8).

To check the report of optical activity the irradiated benzene was again examined in the polarimeter in a 40-cm. cell. The observed rotation was $0.000^\circ \pm 0.002^\circ$, identical with that found for the original unirradiated benzene.

It seems certain, therefore, that although irradiation at the dosage-level described does bring about certain significant effects (colour, spectral change, odour, among others), there is no substantiating evidence from our work that asymmetric genesis of molecules of any optically active material in appreciable amounts has occurred. Since our apparatus was sensitive enough to detect easily 0.005° rotation, this means that for the 40-cm. cell, no effect as great as even 0.2 per cent of that reported by Starodubtsev *et al.* could be found. It seems reasonable, then, to suggest that these workers inadvertently may have had either a contaminated sample or an imperfect polarimeter (in calibration or operation). Their experimental description and apparatus seem simple enough to exclude any unusual irradiation conditions.

We sincerely regret being unable to duplicate the observations of the Soviet workers since the consequences of such validation in the fields of biochemistry, biogenesis, physics, and chemistry would have

been revolutionary and would have revised many of our present concepts of molecular structure, asymmetric induction, electromagnetic interaction, etc.

CHEMISTRY

Strength of Silica Glass

GRIFFITH¹ extrapolated from his experiments the strength of glass to the order of 1,000 kp./mm.², which is many times larger than the strength of the best steel. Orowan² calculated from mechanical principles a value of the same order. More recent measurements, however, gave a much higher value for several silica-glass fibres, namely, 2,460 kp./mm.² (ref. 3); therefore a calculation based on the atomic structure of glass seems to be important.

Starting from the oxygen ion volume v of glass^{4,5}, which is in silica glass 22.70×10^{-24} cm.³, we can calculate the number of oxygen bridges per unit cross-section. The average number of bridging oxygen ions y plus that of the non-bridging oxygen ions x which belong to one silicon ion is 4.

The average number of oxygen ions per net-forming ion (silicon, aluminium, boron, etc.) being R , then:

$$R = O/(Si + Al + B + \dots) = x + y/2$$

since the bridging oxygen ion belongs to two net-forming ions at the same time. From the above relations:

$$y/(x + y) = 2 - R/2$$

The plane of the cube containing an oxygen ion being $v^{1/3}$, the number of oxygen ions per cm.² glass cross-section is $1/v^{1/3}$ and that of the bridging oxygen ions:

$$n = \frac{2 - R/2}{v^{1/3}}$$

The strength of any glass is proportional to n if the glass is really a network of tetrahedra connected with bridging oxygen ions. Silica glass has the smallest R value, 2.00, among all silicate glasses (not containing beryllium, boron, aluminium or other network-forming ions of less than four valencies); therefore it has the highest strength, which is in accordance with the experimental facts.

The distance Si—O in silica is $r = 1.60 \times 10^{-8}$ cm. and there is a Coulomb attraction $-8e^2/r^2$ between Si⁴⁺ and O²⁻. We calculate after Kossel⁶ the work necessary for the separation of an oxygen from the SiO₄ tetrahedron (so that an SiO₃ triangle remains) as the difference of formation energy of an SiO₄ ion $-17.32e^2/r$ and that of an SiO₃ group $-17.08e^2/r^2$, that is, $0.24e^2/r$ per bridging O²⁻ ion or:

$$\frac{0.24(4.80 \times 10^{-10} \text{ e.s.u.})^2}{1.60 \times 10^{-8} \text{ cm.}} = -3.456 \times 10^{-12} \text{ erg.}$$

Fig. 1

In the non-periodic network of glass we approximate the potential function of the pseudo-diatomic molecule SiO₃—O by the potential function of a diatomic molecule with the well-known qualitative form of Fig. 1. At the minimum energy (A) there is equilibrium; if a stretching force is applied, the distance grows until the break of the Si—O bond occurs in the point of inflexion (B).

The potential of the pseudo-diatomic molecule SiO₃—O can be taken approximately as the Morse function:

$$U(r - r_e) = D_e (1 - e^{-\beta(r - r_e)})^2 \quad (1)$$

where U denotes the energy, r_e the distance Si—O in the equilibrium, r the actual nuclear distance, D_e the binding energy in the equilibrium and β a constant. Since at the inflexion point $d^2U/dr^2 = 0$, we get from (1):

$$2e - \beta(r_i - r_e) = 1 \quad (2)$$

where r_i is the nuclear distance in the inflexion point. The force there is:

$$F_i = -\frac{dU}{dr} = [2\beta D_e (1 - e^{-\beta(r - r_e)})e^{-\beta(r - r_e)}]_{r=r_i} \quad (3)$$

The numerical values in this equation are known: $r_e = 1.60 \times 10^{-8}$ cm., $D_e = 0.24e^2/1.60 \times 10^{-8}$ cm. = 3.456×10^{-12} erg = 1.74×10^4 cm.⁻¹ hc.; we need calculate only β . This can be done with the aid of the equation⁷:

$$\beta = 1.2177 \times 10^7 \omega_e \sqrt{\mu_A/D_e}$$

Here μ_A , the reduced mass, must be expressed in atomic weight units ($\mu_A = 13.22$ in the case of the pseudo-diatomic molecule SiO₃—O) and D_e in cm.⁻¹; ω_e is the frequency of the fundamental oscillation. On the basis of the relation⁸:

$$D_e = \frac{\omega_e^2}{4\omega_e x_e}$$

and since the anharmonicity factor of the oscillation found for the ²⁸Si¹⁸O molecule is 4.87×10^{-3} (ref. 9) and taking this value as an approximation for our case, ω_e can be calculated as 339 cm.⁻¹. With

* Small maximum wave (in the absence of maximum suppressor).

ized from similar solutions of the complex by reduction with finely powdered antimony. The reaction scheme is:

The reactions are exothermic and proceed smoothly in a single flask. Yields of $RPCl_2$ from 90 to 55 per cent have been obtained repeatedly for $R = CH_3$ to $R = C_6H_{11}$. Full details of the method and its application in high-activity synthesis of organophosphorus compounds labelled with radioactive phosphorus will be published elsewhere.

Use of Spectrophotometric Evidence for Protein-Dye Binding

SHIFTS in the ultra-violet absorption spectra of aqueous organic solutions of some amino-azo dyes on the addition of buffered protein solutions have frequently been interpreted as evidence of complex formation between protein and dye¹⁻⁴. The effect of the buffer itself on the spectrum of the dye has apparently not always been checked, and the fact that this may influence the results is shown by the following experiments.

The powerful carcinogen dimethyl-*p*-aminoazobenzene and its biologically inactive isomer monoethyl-*p*-aminoazobenzene, purified chromatographically on an activated alumina column, were investigated in approximately 10^{-4} molar solutions in 20 per cent dioxane-water mixtures, between 350 and 550 mμ, using a Unicam SP500 spectrophotometer. Solutions were thermostatted at 25° C. for 24 hr. to attain equilibrium before measuring the spectra at the same temperature.

The spectra of the azo-dye solutions were determined under the following conditions: (1) With the addition of hydrochloric acid (analytical reagent) to give a range of pH 0-5. (2) At pH approximately 6 maintained by the use of acetate, phosphate and phthalate buffers, immediately after preparation of the solutions and at intervals of time up to 24 hr. thereafter. (3) In acetate buffered solution at pH 6, in the presence of 0.1 per cent gelatin, high grade, edible (Imperial Chemical Industries, Ltd.), and of 0.1 per cent bovine plasma albumin fraction V, and on the addition of 5 ml. of concentrated solution of bovine fibrinogen fraction I, pepsin and trypsin (Armour Biochemicals, Ltd.) per 95 ml. of dye solution. (4) In unbuffered solution in the presence of 0.1 per cent bovine plasma albumin. (5) Before and immediately after shaking for 1 hr. with solid bovine plasma albumin and centrifuging off the solid.

The results of these measurements may be summarized as follows: (1) Plots of extinction coefficient against wave-length for solutions of different pH show an isobestic point at 475 mμ for dimethyl-*p*-amino-

azobenzene and at 465 mμ for monoethyl-*p*-aminoazobenzene. The peak in the curves for the latter is shifted towards shorter wave-lengths compared with that for the former, which, according to Kubo⁵, indicates a lesser ability to release electrons. (2) The spectra of the dye solutions with acetate buffer were unchanged after 24 hr., and those of the dye solutions alone were unchanged after several days, showing that dioxane had not affected the spectra. In the case of the phosphate and phthalate buffers there was a marked and progressive shift with time, up to 24 hr. at least, of the peaks of the curves for both dyes, the changes being most pronounced for solutions of dimethyl-*p*-aminoazobenzene. The shifts are similar to those expected from complex formation, but the nature of any such complex and its slow formation in the present systems seem difficult to explain. The phosphate buffer in addition caused some flattening and lowering of the peaks. This normally indicates the removal of the absorbing compound, although it is impossible to state from the present data the way in which this is occurring here. (3-5) In no case was there any change in the dye spectrum on the addition of protein whether to acetate buffered solutions or to the unbuffered solutions.

The pH values of all solutions remained unaltered with time, and observed spectral shifts cannot, therefore, be ascribed to changes in pH.

In view of the observed effects of certain buffers on the spectra of the azo-dyes used here, a re-examination of some of the earlier findings seems desirable, together with a more extensive investigation of the effect of these and other buffer solutions on the spectra of such systems.

BIOCHEMISTRY

Enzymatic Degradation of Deoxyribonucleic Acid into Sub-units

THE generally accepted value for the molecular weight of deoxyribonucleic acid is $6-8 \times 10^6$ (refs. 1 and 2). In the course of a study of methods of preparation involving extraction with solutions of low ionic strength, it has been found that, under a given set of experimental conditions, preparations from chicken erythrocytes could be obtained which showed reproducibly lower molecular weights (Cham-pagne, M., unpublished work). This finding is reminiscent of some results scattered in the literature³ and suggestive of some enzymatic activity involving depolymerization of deoxyribonucleic acid. An investigation was therefore undertaken of the action on deoxyribonucleic acid of preparations from chicken erythrocytes.

Two preparations of deoxyribonucleic acid were mainly used in this work: B1s from calf thymus

($M_w = 6.5 \times 10^6$, $S_{20,w,av}^* = 20S$) and B2 from chicken erythrocytes ($M_w = 8.0 \times 10^6$; $S_{20,w,av}^* = 27.5S$). The crude enzymatic preparations were obtained as follows. Erythrocytes separated by centrifuging one volume of chicken blood, to which half a volume of heparinized 0.15 M sodium chloride - 0.01 M sodium citrate had been added, were lysed with 0.1 per cent saponin in this saline-citrate solvent, then rapidly washed once with distilled water, centrifuged, suspended in distilled water (2.5 vol. per vol. of blood) and shaken overnight in the cold room. The yellowish, viscous, homogeneous suspension was used on the following morning: 1 ml. (containing 3 mgm. nucleoprotein and 3 mgm. protein) was incubated with 30-ml. samples of 0.05 per cent deoxyribonucleic acid in 0.15 M sodium chloride, pH = 5.3.

At the end of digestion, samples were clarified by high-speed centrifugation, then dialysed against M sodium chloride and used for physical measurements and chemical analyses. The final recovery of deoxyribonucleic acid was 80-90 per cent, the losses being accounted for by the co-precipitation of an aliquot of deoxyribonucleic acid with the protein present in the enzymatic preparation.

It was found that very marked changes in the physical properties of deoxyribonucleic acid take place in the first few hours of enzymatic digestion. After 24-48 hr. at 37° C., however, no further significant changes are detectable, even on extending the time of digestion to 120 hr. The molecular weight of the final product was found to be $M_w = 5.5 \pm 0.5 \times 10^6$. The light-scattering results from it are compatible with a solution of monodisperse rods, having a molecular weight per unit length, M/L , of $200 \pm 20/\text{Å}$, a value which is in very good agreement with the Watson and Crick model for deoxyribonucleic acid⁴. A much higher degree of molecular asymmetry in the final, as compared with the starting, product was also indicated by Couette viscosimetry. The behaviour of the sedimentation constant parallels the drop in molecular weight. The value $S_{20,w,av}^* = 5.8S$ finally attained is also indicative of rod-like sedimenting units. Concurrently, the distribution function of sedimentation constants is remarkably narrower in the degraded deoxyribonucleic acid than in the starting preparations.

By using buffers of pH = 4.5-9.0 ($\mu = 0.15$) as solvents for the deoxyribonucleic acid, it was observed that the enzymatic activity shows a very pronounced optimum close to 5.5. No degradation of deoxyribonucleic acid was evident at pH 7.0 or higher, in the presence of 0.03 M magnesium chloride (in 0.15 M sodium chloride, pH 5.3), at ionic strength $\mu = 0.001$ or $\mu = 1.0$ (sodium chloride, pH = 5.3), or when the crude enzymatic preparation had been previously kept 5 min. at 100° C.

It was also possible to show that, during the enzymatic digestion, no dialysable nucleotides were produced, and no significant changes of the absorption coefficient at 260 m μ were detectable. No differences were found between degraded B1s and B2, although the degradation of the former was slower than that of the latter.

It is evident from the above results that the fragments obtained by the enzymatic digestion of deoxyribonucleic acid investigated in this work do not originate in a random breakdown. All available experimental evidence suggests that they are true sub-units of the larger deoxyribonucleic acid particle, $M_w = 6-8 \times 10^6$. How these sub-units are bound

together, what is the nature of their end-groups and whether they possess the same biological properties as the parent molecules are not yet known, and are now being investigated. It is likely, however, that the rod-like sub-units are connected in an end-to-end arrangement by some 'flexible joints' (sites of the enzymatic action) to form the larger deoxyribonucleic acid particle. It has already been shown that the light-scattering data for the latter are compatible with such a model⁵.

Effect of Glucose Concentration on Respiration of Rous Sarcoma and of Chorioallantoic Membrane

CRABTREE'S initial observation that glucose will depress the oxygen consumption of tumour cells has prompted further investigations of this phenomenon, most particularly in Ehrlich ascites cells¹ and in reconstructed systems². It has been recently reported³ that the virus-induced Rous sarcoma on the chorioallantoic membrane of chicken embryos shows a 'Crabtree effect'. The present communication reports the effect of glucose at various concentrations on the respiration of normal chorioallantoic membrane, and of Rous sarcoma growing on it, and extends the initial observations in this system to other parameters of glucose metabolism.

Standard lot CT 842 of Rous sarcoma virus was obtained from Dr. W. Ray Bryan and was stored in a 'dry-ice' chest until used. An inoculum of 0.2 ml. at a dilution of one-tenth of thawed virus in cold sterile saline solution containing 2 per cent inactivated horse-serum was dropped on to the chorioallantoic membranes of chicken embryos 9-10 days old by the false air-sac technique. Incubation at 36° C. during 6-7 days yielded Rous sarcoma. Control chorioallantoic membrane was prepared in the same manner except that virus was not added to the inoculum.

Chorioallantoic membranes used as normal controls were excised aseptically from embryos 16-17 days old. The tissue was cut into small pieces and washed thoroughly in cold saline. Tissue pieces of approximately 1 cm. square were removed from washing solution, blotted briefly on filter paper, and approximately 200 mgm. of wet tissue was added to each Warburg vessel. Rous sarcoma was dissected free of non-tumorous tissue and sliced with a Stadie-Riggs hand microtome. Tissue slices were washed likewise in cold saline and blotted on filter paper.

Tissues were incubated in a final volume of 2 ml. with Hanks's balanced salt solution in the absence of added bicarbonate, and without phenol red indicator. The pH was adjusted to 7.6 with dibasic phosphate (M/15). Glucose concentration in the medium was

Table 1. OXYGEN CONSUMPTION OF NORMAL CHORIOALLANTOIC MEMBRANE AND OF ROUS SARCOMA GROWN ON CHORIOALLANTOIC MEMBRANES

All values are expressed as μ l of gas per mgm. dry tissue per 4-hr. incubation period. Each value represents the average of duplicate determinations

Initial glucose (μ moles/ml.)	0	2.5	10	50
Chorioallantoic membrane	17.8	22.0	18.8	18.4
	18.0	21.0	16.8	18.4
	17.6	21.0	16.4	17.2
Rous sarcoma	7.2	5.6	7.2	0.0
	9.2	5.2	4.8	3.6
	8.6	4.4	5.2	5.6

varied from 0.5 to 50 mM. Air was the gas used in this manometric work. Initial and final glucose concentrations were determined on aliquots from the reaction vessels.

The manometric results of uninfected chorioallantoic membrane and of chorioallantoic membrane infected with Rous sarcoma virus are summarized in Table 1 and in Fig. 1. While glucose was without effect in depressing the oxygen consumption of chorioallantoic membrane, the respiration of Rous sarcoma was depressed by all concentrations of glucose tested. The results (Fig. 1) are suggestive of an increased depression of oxygen consumption with an increase in glucose concentration from 0.5 to 1.0 mM.

Fig. 1. Respiration of Rous sarcoma and chorioallantoic membrane in the absence and presence of glucose (0.5 and 1.0 μ moles/ml.). Each curve represents the mean of three experiments

Respiration of the tissue was linear over a 5-hr. period, and no diminution of the glucose effect was observed with time. No further decrease in oxygen consumption of Rous sarcoma was observed with concentrations of glucose greater than 1 mM.

The utilization of glucose by both the chorioallantoic membrane and the Rous sarcoma was increased with increasing concentrations of medium glucose (Table 2). The Rous sarcoma uses much more glucose than the chorioallantoic membrane. However, the degree of depression of oxygen consumption observed in the Rous sarcoma is not necessarily related to the glucose utilization, that is, an increase in glucose utilization from 0.12 to 1.01 μ moles per mgm. dry tissue per 4 hr. did not result in increased depression of oxygen consumption.

Table 2. EFFECT OF SUBSTRATE CONCENTRATION ON GLUCOSE UPTAKE BY NORMAL CHORIOALLANTOIC MEMBRANE AND ROUS SARCOMA GROWN ON THE CHORIOALLANTOIC MEMBRANE

All values are expressed as μ moles per mgm. dry tissue per 4-hr. incubation period. Each value given is the average of six experiments

Initial glucose (μ moles/ml.)	2.5	10	50
Chorioallantoic membrane	S.E. ± 0.08	± 0.17	± 0.09
	± 0.01	± 0.03	± 0.09
Rous sarcoma	S.E. ± 0.12	± 0.81	± 1.01
	± 0.01	± 0.04	± 0.06

Thus it would appear that the Rous sarcoma virus offers a means of investigating the metabolic events in the induction of neoplastic growth. A comparison of biochemical changes between infected and non-infected cells is expected to reveal differences existing between normal and neoplastic tissues. The Rous sarcoma system offers a means by which sequential metabolic alterations may be observed during tumour development and growth.

The effect of glucose present at various concentrations has been investigated in Ehrlich ascites cells^{1,2}. McKee *et al.*⁴ have reported that glucose at very low concentrations stimulates oxidative metabolism of these cells and inhibits oxidative metabolism at higher concentrations. Glucose in 5.5 mmoles quantity produces a 'Crabtree effect' in ascites cells during the first hour of incubation, but the depression of oxygen consumption is not observed after this time, during which all the medium glucose was utilized. Block-Frankenthal and Ram⁵ have observed no 'Crabtree effect' in ascites cells incubated with 2.5 mmoles of glucose, but a depression of oxygen consumption occurs with 10 mmoles. Further, it has been observed that with 2.5 mmoles of glucose, Ehrlich ascites cells completely utilize all the substrate during the initial equilibrium period⁶. Differences in effective concentrations of substrate in the ascites tumour and the Rous sarcoma may be due in part to the rate with which glucose of the same concentration (2.5 mM.) was utilized. Rous sarcoma uses less than 50 per cent of the added glucose during a 4-hr. incubation period.

Since the Rous sarcoma utilizes appreciably more glucose than the normal chorioallantoic membrane control, the possibility exists that a decreased rate of oxygen consumption by the tumour may be the result of increased glucose utilization.

It has been proposed that increased glycolysis may inhibit oxygen consumption by reducing the intracellular concentrations of inorganic phosphate and adenosine diphosphate⁷. Considering only tumour tissue, it would appear that within certain limits an increase in glucose will cause a further depression of oxygen consumption. However, if the effect of this sugar on the metabolism of normal cells is considered it would appear unlikely that glucose utilization *per se* can depress uptake of oxygen, since increasing the concentration of the substrate in the medium containing normal tissue will increase glucose utilization without changing the respiration.

Crystalline Dihydropteroylglutamic Acid

THE preparation of dihydropteroylglutamic acid has previously been described by O'Dell *et al.*, who used catalytic hydrogenation of pteroylglutamate¹, and by Futterman, who carried out the reduction with sodium dithionite². The acid prepared by catalytic hydrogenation is unsuitable for many biochemical studies, however, because it contains traces of tetrahydropteroylglutamic acid³. The material obtained by the method of Futterman is an amorphous discoloured preparation³, but was found to be uncontaminated by tetrahydropteroylglutamic acid³. No analytical figures have been given for this material. By reducing purified pteroylglutamate with sodium dithionite according to the method of Futterman and twice precipitating the product by slow adjustment of the pH between strictly defined values, it has now been found possible to obtain dihydropteroylglutamic acid consistently as a white crystalline product giving analytical results agreeing fairly well with the theoretical values.

The procedure adopted was as follows. Ascorbic acid (1 gm.) was dissolved with mechanical stirring in about 5 ml. of water in a 25-ml. beaker. While stirring continued and continuous readings of the pH were made with a glass electrode 1 N sodium hydroxide was added slowly until the pH rose to 6.0. The volume of the solution was brought to 10 ml. by the addition of water and a solution of 38.2 mgm. of pteroylglutamic acid (purified as previously described⁴) in 1.6 ml. of 0.1 N sodium hydroxide added. Mechanical stirring was recommenced and 400 mgm. of solid sodium dithionite added. When all the dithionite had dissolved stirring was continued slowly for 5 min. at room temperature (22–25°). An ice-bath was then placed around the beaker and stirring continued until the temperature had fallen below 5°. Addition of 1 N hydrochloric acid from a burette at a rate of approx. 0.1 ml./min. was then commenced while the solution was stirred rapidly at 0–5°. Addition of hydrochloric acid was continued until the pH fell to 2.8 (approx. 5 ml. of 1 N hydrochloric acid required). After stirring the solution for a further 5 min. to allow complete precipitation, the precipitate was recovered by centrifugation (5 min. at 1,000g, temperature 0°) and the supernatant discarded. The precipitate, which was

Fig. 1. Crystals of dihydropteroylglutamic acid ($\times c. 1,330$)

Fig. 2. Absorption spectra of solutions of crystalline dihydropteroylglutamic acid (0.03 mM) in 0.1 M potassium phosphate buffer (—); in 0.01 N sodium hydroxide (---); and in 0.1 N hydrochloric acid (-.-.-)

mainly amorphous but contained some crystalline material, was re-suspended in 10 ml. of an ice-cold solution of 10 per cent sodium ascorbate, pH 6.0, freshly prepared as previously described. The suspension was returned to a 25-ml. beaker cooled in a ice-bath and mechanical stirring and continuous pH measurement recommenced. The bulk of the precipitate redissolved at this stage and the solution was between pH 5 and 6. If necessary the solution was adjusted to pH 6 by cautious addition of 1 N sodium hydroxide, and maintained at this pH while being stirred at 0° for a further 5 min. Under these conditions only crystalline material remained undissolved, causing marked birefringence. The dissolved dihydropteroylglutamic acid was crystallized from the solution by slow addition of 1 N hydrochloric acid performed exactly as previously. When crystallization was complete (5 min. after reaching pH 2.8) the heavy, white, birefringent suspension was centrifuged off as before and washed three times with ice-cold 0.001 N hydrochloric acid by suspending and centrifuging. After pipetting off the final supernatant the precipitate was quickly dispersed over the walls of the centrifuge tube, placed in a desiccator over phosphorus pentoxide and potassium hydroxide and the pressure quickly reduced to 0.02 mm. mercury. The solid, which was initially white, was stored in the desiccator in the dark until required. It became discoloured while stored in this way over a period of days, and discoloured even more rapidly when removed from the desiccator. Under the microscope the crystals appeared as fine, very small needles (Fig. 1). After preparation, a sample for analysis was dried for 16 hr. over phosphorus pentoxide (pressure 0.02 mm. mercury) at 25°, rather than at higher temperatures, in order to avoid decomposition. Calculated for $C_{15}H_{21}O_6N_7 \cdot 2\frac{1}{2}H_2O$: C, 46.72; H, 5.37; N, 20.08 per cent. Found: C, 47.57; H, 5.62; N, 19.61

per cent. Absorption spectra for the crystalline material are shown in Fig. 2.

Identification of 19-Norandrostenedione in Follicular Fluid

DURING the course of a recent investigation of the steroids present in the follicular fluid of the mare¹, an unidentified $\alpha\beta$ -unsaturated 17-ketosteroid was detected, and it seemed possible that this might represent one of the intermediates in the conversion of androst-4-ene-3,17-dione (androstenedione) to oestrone.

Further work on this compound has now established its identity as 19-norandrost-4-ene-3,17-dione (19-norandrostenedione), the evidence being as follows: (1) R_F value of the unknown compound identical with that of authentic 19-norandrostenedione in ligroin/80 per cent methanol and hexane: benzene/formamide paper chromatographic systems; (2) ultra-violet, sulphuric acid and sulphuric acid-ethanol chromogen spectra of the unknown identical with those of authentic 19-norandrostenedione; (3) R_F value of the sodium borohydride reduction product of the unknown identical with the R_F value of 19-nortestosterone in a ligroin/80 per cent methanol chromatographic system; (4) R_F value of the acetate of this reduction product identical with that of 19-nortestosterone acetate in ligroin/80 per cent methanol and hexane/formamide systems; (5) failure of the unknown to be oxidized by chromium trioxide in pyridine, or acetylated by acetic anhydride in pyridine; (6) Zimmermann colour reaction of the unknown identical with that of authentic 19-norandrostenedione; (7) infra-red spectrum of the unknown identical in every respect with that of authentic 19-norandrostenedione.

Since there still remained the possibility that this compound might have been an artefact produced by the action of alkali on 19-hydroxyandrost-4-ene-3,17-dione, 20 μ gm. of the latter substance was added to a sample of follicular fluid prior to extraction; however, this did not increase the amount of 19-norandrostenedione present in the final extract.

With the exception of two oestradiols reported by Marker *et al.*² in non-pregnant human urine, this is the first time that a non-aromatic 19-nor steroid has been found as a natural product. The mean concentration in eight samples of equine follicular fluid was 20 μ gm./100 ml. fluid (range 4–45 μ gm./100 ml.), and since it is present in considerable amounts, it is interesting to consider its possible biological significance.

It is now well established that androstenedione serves as a precursor in the biosynthesis of oestrogens, and as a result of *in vitro* studies with a number of endocrine tissues, it was suggested³ that 19-hydroxyandrostenedione was an intermediate in this conversion. This has now been amply confirmed^{4,5}, and it has been shown that human placental microsomes *in vitro* can convert androstenedione to oestrone via 19-hydroxyandrostenedione. Since 19-oxoandrostene-

dione is also readily converted to oestrone, the following biosynthetic sequence has been proposed⁶:

If the results of these *in vitro* experiments with human placental microsomes are an accurate reflexion of the events taking place in the ovary *in vivo*, one might expect to find 19-hydroxyandrostenedione and 19-oxoandrostenedione in follicular fluid. However, this is not the case; repeated attempts to identify 19-hydroxyandrostenedione in large quantities of equine follicular fluid have met with negative results, although recoveries of the pure steroid are satisfactory. Neither is there as yet any evidence to suggest that 19-oxoandrostenedione is present in equine follicular fluid. These negative results could be ascribed to the fact that both intermediates are so rapidly converted to oestrone that they do not accumulate in the ovary. It would be tempting to conclude that in the mare's ovary 19-norandrostenedione serves as an alternative intermediate in the conversion of androstenedione to oestrone. However, it must be remembered that 19-nortestosterone is a relatively inefficient oestrogen precursor *in vitro*⁴.

I wish to express my thanks to Dr. R. K. Callow and Mr. Paul Miners for carrying out the infra-red analysis. Reference samples of 19-hydroxyandrostenedione and 19-norandrostenedione were kindly supplied by Dr. Maximilian Ehrenstein (Philadelphia) and the Medical Research Council Steroid Reference Collection (Dr. W. Klyne).

Isolation of Purified Trichophytin

COMMERCIAL preparations of trichophytin¹ are generally aqueous extracts of the fungal mycelium (for example, *Trichophyton mentagrophytes*) together with a proportion of the culture medium. They thus contain a variety of substances which are not specific to trichophytin sensitivity and which may contribute in a variety of ways to the production of the skin reaction. In order to limit this non-specific response and to define the significance of the trichophytin reaction, an attempt has been made to isolate the antigenic material in a purified form and to obtain preliminary data as to its constitution.

The fungus, *Trichophyton mentagrophytes* (N.T.C. D281), was grown in a medium containing glucose (50 gm.), 1 per cent ammonium sulphate (100 ml.), 1 per cent sodium nitrate (100 ml.), 5 per cent acid hydrolysed casein (100 ml.), trace metal ions (1 ml.; ferrous sulphate, 200 mgm.; manganous sulphate, 100 mgm.; zinc sulphate, 100 mgm. in water, 100 ml.) and solutions A (540 ml.) and B (105 ml.) of

Krebs-Ringer phosphate². After 4-6 weeks, the mycelium was collected, rinsed in distilled water and dried with acetone. Batches of this material were then extracted severally in an 'Ato-mix' with a variety of solvents including *M* sodium chloride, 5 per cent trichloroacetic acid and ethylene glycol, filtered through 'Filtercel', dialysed and freeze-dried. All such extracts were antigenically active, but that produced by ethylene glycol extraction ('crude trichophyitin') was preferred, since it combined high antigenicity with a low irritant content as determined on sensitized and control guinea pigs. The quantitative yield of 'crude trichophyitin' from the acetone-dried mycelium was approximately 10 per cent using two extractions, 80 per cent of this being obtained in the initial extract. Crude trichophyitin contained carbohydrate³ and protein⁴ in the ratio 10:1 (glucose and crystalline egg albumin as standards). Separation of crude trichophyitin by paper electrophoresis in borate buffer pH 10 and treatment with the periodate-Schiff's reagent usually showed one major component together with an occasional faint second band moving rather faster towards the anode.

Purification of 'crude trichophyitin' was effected by precipitation as a borate-'Cetavlon' complex⁵. Crude trichophyitin was dissolved in water (500 mgm./30 ml.) and equal volumes of 'Cetavlon' (B.D.H. 10 per cent) and borate buffer (pH 7, 1 per cent) added. *N* sodium hydroxide was then added until precipitation occurred (pH 9-10). The precipitate was washed with water, dissociated by solution in 2 *N* acetic acid and poured into ethanol. The resulting precipitate was washed successively with acetic acid-ethanol mixture, ethanol, ether, and dried ('Cetavlon' precipitated fraction). Any borate and 'Cetavlon' ions which remained were removed by passing an aqueous solution down a column of 'Zeokarb 225 (H⁺)', dialysing the eluate and recovering the active material by freeze-drying to give purified trichophyitin. The non-specific elements of the reaction, indicated by control animals, were almost completely eliminated while the biological response of both 'immediate' and 'delayed' reactions were practically undiminished, in guinea pigs sensitized by the injection of powdered sterile mycelium suspended in Freud's adjuvant (Table 1). Testing solutions could be ampouled and boiled for sterilization, thus avoiding the use of preservatives. Such 'purified trichophyitin' showed only one component on paper ionophoresis in borate buffer pH 10.

Table 1. PURIFICATION OF TRICHOPHYTIN

Fraction	Guinea pig	Mean delayed reaction diameters $\pm$ S.E. at concentration of 0.2 mgm./ml.
Ethylene glycol extract (crude trichophyitin)	Sensitized	10.8 $\pm$ 0.8
	Control	4.5 $\pm$ 0.9
'Cetavlon' precipitated fraction	Sensitized	8.6 $\pm$ 0.8
	Control	2.4 $\pm$ 0.4
Purified trichophyitin	Sensitized	9.3 $\pm$ 1.5
	Control	0 $\pm$ 0

Special care was taken in the removal of the 'Cetavlon' since although the detergent itself appeared innocuous when skin tested in humans at a concentration of 0.1 mgm./ml., its complex with trichophyitin produced violent skin reactions. This effect was not apparent when the preparation was first tested in guinea pigs. Passage down 'Zeokarb 225 (H⁺)' ensures the complete removal of all the 'Cetavlon' and allows the purified trichophyitin to be tested with confidence.

Ultracentrifugal analysis of trichophyitin indicates that it has a relatively low molecular weight: 20,000-30,000. Chromatographic analysis of its hydrolysate showed it to contain glucose, mannose and the amino-acids leucine, valine, alanine, glycine, serine, threonine, glutamic acid, aspartic acid and arginine. Evidence from optical rotation ($[\alpha]_D + 88^\circ$ in water) and infra-red spectra (absorption at 838 cm.⁻¹) indicated that these sugar residues (equivalent^{6,7} to an 80 per cent polysaccharide content) were linked α -glycosidically. The purified trichophyitin stained blue ($\lambda_{\max}$, 600 m μ) with iodine. Since this property was destroyed by incubation with α -amylase although antigenic activity was still retained, some at least of the glucose residues were probably present in a mould starch impurity. The ultra-violet absorption spectra of purified trichophyitin showed a shallow peak at 270-280 m μ corresponding approximately to a 10 per cent peptide content. Trichophyitin contained nitrogen 1.05 per cent (Kjeldahl). Peptide linkages were indicated by infra-red absorption peaks at 1,634 cm.⁻¹ (C=O) and 1,510 cm.⁻¹ (N-H) since *N*-acetamido sugars⁸ were absent. Purified trichophyitin was found to be free from nucleic acid^{9,10}.

We are indebted to Dr. C. N. D. Cruickshank and Prof. M. Stacey for their interest in this work, and Dr. S. R. Wood for the biological testing.

The Pigment of *Phoma terrestris* Hansen

SOME years ago Kögl *et al.*¹ reported the isolation from the fungus *Phoma terrestris* Hansen of a pigment which was named phomazarin. On the basis of degradation studies structure (I) was adopted for this pigment:

This representation attributed to phomazarin an aza-anthraquinone nucleus which would make it unique among natural products.

Accordingly, we have re-examined a culture of *Phoma terrestris* Hansen, obtained from the Central-

bureau voor Schimmelcultures (Baarn), and grown exactly as described by Kögl. There was isolated from the mycelium, by simple extraction processes, about 1 per cent by weight of cynodontin (II), m.p. 260° (found: C, 63.1; H, 3.9; $C_{15}H_{10}O_6$ requires C, 63.0; H, 3.5 per cent), readily identified as its tetra-acetate, by its infra-red spectrum, and by comparison with an authentic specimen kindly provided by Sir Alexander Todd.

Our experiments suggest the presence of at least one other pigment, but of no compound resembling phomazarin.

HISTOCHEMISTRY

Enzymes Histochemically Demonstrable in the Earliest Phase of Wound Healing

DURING my work on local reactions in acutely injured skin, I was attracted by the early appearance of certain enzymes in the healing wound. Most authorities consider that in wound healing there is initially a metabolically inert lag phase of 1-4 days duration. Relatively little is known about the first appearance of enzymes during this phase. Balazs and Holmgren¹ found alkaline phosphatase at the wound margin 24 hr. after the injury. Fell and Danielli² and Firket³ demonstrated during the lag phase that this enzyme was only present in the invading polymorphonuclear leucocytes. Needham⁴ considered that acid phosphatase probably plays no part in repair. To the best of my knowledge there has been no previous report of the distribution of leucine aminopeptidase during the lag phase of healing.

I made an experimental study on guinea pigs, cutting circular skin wounds, 5 mm. in diameter, in a closely shaved dorsal area. The skin inside the circle was excised with fine scissors and the wounds were not covered. Groups of animals were killed $\frac{1}{2}$, 1, 2, 4, 8, 16, 32, 64 and 128 hr. after wounding, and a flap of skin containing the circular wound was removed immediately. One-half of each skin flap was fixed overnight in cold neutral 10 per cent formalin. Cryostat sections, 10 μ in thickness, of these halves were used for the histochemical demonstration of phosphatases. By means of coupling azo dye techniques, acid phosphatase⁵ activity was visualized at pH 5.0 and alkaline phosphatase⁶ at pH 9.2. The other half of the skin flap was frozen fresh and cryostat sections of it were stained for leucine aminopeptidase⁷.

Leucine aminopeptidase activity was found to be present as little as 2 hr. after the injury (Fig. 1), gradually increasing up to 32 hr. There was a distinct positive area in the dermis a little beyond the wound edge. In addition to this, the lower layers of the stratum Malpighii showed moderate activity.

A little beyond the edge of the wound a clearly distinguished dermal zone exhibited strong acid phosphatase activity, beginning in a 4-hr. wound (Fig. 2) and increasing up to 16 hr. The uninjured

Fig. 1. Leucine aminopeptidase activity in a 2-hr. wound

epidermis showed intense activity all through the stratum Malpighii.

An active zone in the vicinity of the injured dermis could also be demonstrated in an 8-hr. wound by the technique for alkaline phosphatase (Fig. 3). The activity increased up to 32 hr. None of the epidermal strata nor the hairs showed any demonstrable alkaline phosphatase activity in the uninjured skin.

Except for some solitary invading polymorphonuclears, no distinct leucocytic zone was visible until 16-32 hr. had elapsed. These cells occupied almost the same area as had shown intense activity of enzymes much earlier. Thus leucocytes cannot be

Fig. 2. Acid phosphatase activity in a 4-hr. wound

Fig. 3. Alkaline phosphatase activity in an 8-hr. wound

the main source of these enzymes. On the other hand, the most severely injured inner area of the wound showed no demonstrable enzyme activity. Consequently I suppose that the enzymes are not passively released by the seriously damaged cells in the innermost part of the wound. By contrast, in the outer zone the local cells are still able actively to produce enzymes in large amounts. The slight injury to the outer zone might serve as a stimulus activating local defence forces.

Besides functioning as a defence barrier, the enzymes appearing in the outer zone of the wound periphery may play a part in more specific regenerative processes. A synthetic action has been ascribed to leucine aminopeptidase⁸, acid phosphatase⁹ and alkaline phosphatase¹⁰. It seems probable, therefore, that the production of these enzymes represents one of the first steps in the repair process starting early in the so-called lag-phase of wound healing.

A more detailed investigation is in progress, the results of which will be published elsewhere.

PHYSIOLOGY

Argininosuccinase Activity in Brain Tissue

A NEWLY recognized form of mental deficiency, probably caused by an inborn error of metabolism, has been described¹. The unknown metabolite, now known to be argininosuccinic acid², found in this disease was present in the plasma, cerebrospinal fluid and urine. The concentration of this amino-acid was higher in the cerebrospinal fluid than in the plasma, suggesting that the compound is formed in the brain or some other organ in close association with the fluid. Apart from these patients, argininosuccinic acid has never yet been found, even in traces, in plasma, cerebrospinal fluid or urine of man or rats, nor can it be detected in extracts of rat liver, kidney or brain.

The compound was first described by Ratner, Petrack and Rochovansky³ as an intermediate in the urea-cycle. Ratner and her colleagues described two enzyme activities concerned with metabolism of argininosuccinic acid present in liver and kidney tissue^{4,5}. We have found that one of these, argininosuccinase, which catalyses the reaction:

is also present in homogenates of rat brain, spleen and blood cells (but not in plasma) and in ox retina. Walker⁶ has also reported argininosuccinase activity in brain, testis, spleen, pancreas, thymus, heart and skeletal muscle of the dog.

Argininosuccinic acid can be separated from other amino-acids by high-voltage electrophoresis on filter paper at pH 5 (ref. 7). Using this technique it can be demonstrated that argininosuccinic acid is formed when homogenates of the above tissues are incubated with arginine and fumaric acid at pH 7.5 and that ornithine is formed when the homogenates are incubated with argininosuccinic acid in the presence of added arginase.

A method similar to that described by Ratner⁸ was used to estimate the argininosuccinase activity in rat brain and liver and also to study its distribution in various regions of the brain. A series of tubes, each containing 50 μ M potassium phosphate buffer pH 7.5, arginase, at least 6 Van Slyke-Archibald units⁹, and 3–15 μ M argininosuccinic acid, in 0.5 ml., were prepared and warmed to 37° C. Rat tissue, obtained immediately after the death of the animal, was homogenized in seven volumes of ice-cold water or 0.1 M potassium phosphate buffer, pH 7.5. The homogenate was brought to 37° C. 1.0 ml. of 20 per cent metaphosphoric acid was added to the first tube followed by 0.5 ml. of homogenate. This tube was used for the zero value. 0.5 ml. homogenate was added to each of the other tubes, which were left to incubate at 37° C. for suitable intervals of time (for brain 20, 40, 60 min. during which time urea production was linear) before the reaction was stopped by the addition of 1.0 ml. of metaphosphoric acid. After centrifuging, urea was estimated in 0.5 ml. of the supernatants using Archibald's method as described by Ratner⁸, except that 2.0 ml. acid reagent and 0.1 ml. of a 3 per cent alcoholic α -isonitrosopropiophenone solution were used. Two series of control tubes: (1) as for whole system minus argininosuccinic acid; (2) as for whole system minus homogenate, were run simultaneously.

Argininosuccinase activity was calculated from the urea formed in the experimental series, minus that of

the controls. From eight estimations, using male rats of the Wistar albino strain weighing 150–180 gm., the average activity of brain tissue was $2.2 \mu\text{M/hr.}/\text{gm.}$ wet tissue (standard deviation 0.6) and for liver $200 \mu\text{M/hr.}/\text{gm.}$ wet tissue (standard deviation 80). The activity observed in blood is less than 5 per cent of that of the brain of the same animal, so the activity observed for the brain cannot be attributed to included blood.

Using pig brain, all regions, so far as can be determined on a macro-scale, as well as the spinal cord and the meninges have some argininosuccinase activity. The cerebrum has only 40 per cent and the brain stem 70 per cent of the activity of the cerebellum per gram wet tissue (Table 1). An attempt has been made to localize further these activities. No difference could be found in the various regions of the cerebrum; but the white matter always had lower activity than the grey. A similar difference in activity between the white and grey matter of the cerebellum was not observed. The arginase activity of the pig brain homogenates was also determined, and was found to be distributed differently. The cerebrum and cerebellum have approximately the same activity and in both the activity is greater in the grey than in the white matter. This difference is eliminated if the arginase activity is determined in the presence of added manganese.

Table 1. DISTRIBUTION OF ARGININOSUCCINASE AND ARGINASE ACTIVITIES IN PIG BRAIN

Region	Argininosuccinase ($\mu\text{M/hr.}/\text{gm.}$ wet tissue)	Arginase ($\mu\text{M/hr.}/\text{gm.}$ wet tissue)
Whole brain	1.5	10.1
Cerebrum, grey	1.3	11.6
white	0.9	8.6
Cerebellum	3.2	11.9
Brain stem	2.3	7.3

The observed distribution of argininosuccinase activity in brain tissue (though it may be due to the distribution of an unrecognized co-factor, or to an inhibitor) is probably a reflexion of the cell densities of the various regions. It seems likely, however, that the activity of some cell types may be greater than others, for the cerebellar activity is only 2.5 times that of the grey cerebrum, whereas Nurnberger and Gordon¹⁰ have shown that the total cell density of the cerebellum is about four times greater than that of the grey cerebrum. Similarly, when considered on a cell basis using the data of Nurnberger and Gordon for total cell density, the activity of the liver per cell is only 45 times as great as that of the brain.

Sporn, Dingman, Defalco and Davies^{11,12} have recently shown that urea can be synthesized by rat brain *in vivo*. Argininosuccinase is one of the enzymes of the urea cycle, as modified by Ratner, so it seems likely that some at least of the urea produced by the brain may be formed by a mechanism similar to that of the liver. (Ratner has evidence for the occurrence of argininosuccinase and also of the condensing enzyme responsible for synthesizing argininosuccinic acid from citrulline and aspartic acid in the brains of rats, steers and monkeys—private communication.) It has been suggested that the primary function of the ornithine 'cycle' may be the synthesis of arginine and citrulline¹³ rather than of urea. If the complete set of enzymes does exist in the brain, such a function would be particularly interesting.

One of us (S. T.) wishes to thank the Mental Health Fund for a grant which enabled her to carry

out this work. She would also like to thank Dr. L. M. Kerly for her advice and constant encouragement.

An Effect of Insulin on Production of Glucose during Hepatic Glycogenolysis

IN earlier work the effect of a prolonged intravenous infusion of insulin on the utilization and production of circulating glucose was investigated in the trained, unanaesthetized normal dog in the post-absorptive state with the aid of intravenously administered ^{14}C -glucose¹. The plasma glucose concentration and specific activity were determined at frequent intervals, and from these values were calculated the rates of production of hepatic ^{12}C -glucose and total glucose-uptake by the tissues². It was shown that insulin brought about a hypoglycaemia primarily by increasing the uptake of glucose by the tissues. The rate of production of hepatic ^{12}C -glucose, although temporarily somewhat reduced soon after the insulin infusion was begun, usually rose during the course of the infusion to higher than normal levels, but not sufficiently to restore the plasma glucose concentration to its pre-insulin level. When the insulin infusion was stopped, there was a marked further increase in the production of hepatic ^{12}C -glucose which restored the plasma glucose concentration to its control-level. From these findings it was concluded that, during the period of insulin infusion, the production of ^{12}C -glucose was restrained in spite of severe hypoglycaemia¹.

To elucidate this effect of insulin, experiments have been carried out in which production of hepatic ^{12}C -glucose was raised by treatment with phloridzin or glucagon prior to the infusion of insulin. Phloridzin, injected subcutaneously in normal dogs in the post-absorptive state 2 hr. prior to administration of ^{14}C -glucose, caused a marked glucosuria which continued throughout the experiment. However, the plasma glucose concentration was maintained at near the normal level by a several-fold increase in production of hepatic ^{12}C -glucose. An insulin infusion (0.07–0.14 u./kgm./hr., intravenous) started 4 hr. after the phloridzin injection reduced production of hepatic glucose to about the pre-phloridzin level. When the insulin infusion was stopped, the production of hepatic

glucose rose again to its high pre-insulin level. The plasma glucose concentration was reduced as usual by insulin and rose when the insulin infusion was stopped³.

In an attempt to eliminate liver glycogen as a source of the ^{12}C -glucose produced by the liver, normal dogs were depleted of liver glycogen by a 2-day fast and continuous phloridzination during the last 24 hr. of the fasting period. These animals exhibited a glucosuria, moderate hypoglycemia and normal or slightly raised rate of production of hepatic ^{12}C -glucose. The infusion of insulin (0.07–0.14 u./kgm./hr., intravenous) lowered the concentration of plasma glucose, but did not reduce production of hepatic ^{12}C -glucose, in contrast with the effect of insulin in acutely phloridzinized dogs.

In view of these findings, the effect of insulin was studied in normal dogs in the post-absorptive state while hepatic glycogenolysis was being stimulated by glucagon. The infusion of glucagon (4 $\mu\text{gm.}/\text{kgm.}/\text{hr.}$, intravenous) markedly increased production of hepatic ^{12}C -glucose and raised the concentration of plasma glucose. An insulin infusion (0.14–0.33 u./kgm./hr., intravenous), superimposed on the glucagon infusion, lowered the elevated rate of production of hepatic ^{12}C -glucose. On termination of the insulin infusion, with continuation of glucagon administration, the rate of production of the hepatic ^{12}C -glucose and the plasma glucose-level increased again.

These observations demonstrate that insulin promptly inhibits production of glucose at times when hepatic glycogenolysis is taking place and fails to do so when liver glycogen has been depleted and when the production of glucose by the liver probably originates by gluconeogenesis (namely, the 2-day fasted, phloridzinized animal). It can be inferred from these observations that insulin should reduce the net breakdown of hepatic glycogen brought about by glycogenolytic agents. Earlier evidence for such an effect of insulin has been reviewed by Cori⁴.

The restraining effect of insulin, described earlier, is presumably exerted by a similar mechanism. Thus, when the concentration of blood glucose is lowered by a continuous infusion of insulin, release of physiological glycogenolytic agents is evoked by the hypoglycemia. So long as the infusion of insulin continues, the ability of these agents to bring about liver glycogenolysis is limited. When the insulin infusion is terminated, this restraint is removed, and the resulting increased glycogenolysis causes a marked increase in the production of ^{12}C -glucose.

The small temporary effect of insulin in reducing production of hepatic ^{12}C -glucose, which we have observed when an insulin infusion is first begun, could be due to a similar effect of insulin on that small portion of the production of glucose which is arising by hepatic glycogenolysis in the normal unanesthetized dog in the post-absorptive state. It is also conceivable that dogs with initially high blood-sugar-levels due to fright or anaesthesia or dogs having impaired hepatic circulations and maintained on high carbohydrate diets might have larger fractions of their production of hepatic glucose derived from glycogenolysis, and that this might be responsible in some part for the larger initial inhibitory effects of insulin on the production of hepatic glucose which have been reported by others.

The present observations do not permit a definite conclusion as to the mechanism whereby insulin reduces the production of glucose during hepatic glycogenolysis. Interference with phosphorylase action would produce the findings observed; however, stimulation of glycogen synthesis via the uridine

diphosphate glucose pathway⁵ could also bring about a net decrease in glucose production, but any mechanism of this kind would have to include a special provision to account for the fact that a decrease in production of glucose is observed only during glycogenolysis. Whether insulin exerts an inhibitory effect on production of glucose by acting directly on the liver or by indirect means cannot be stated at the present time.

The present experiments suggest that insulin administered to the intact animal promptly inhibits production of hepatic glucose when glycogenolysis is taking place or is being called for by glycogenolytic factors evoked by hypoglycemia. This action of insulin would appear to be of physiological significance.

Production of Free Water in the Mammalian Foetus

THE hypotonicity of the foetal fluids and urine of many mammalian foetuses is well known¹, and attempts have been made to explain it in terms of active transport of water or of sodium². In certain conditions, the production of osmotically free water may be the physico-chemical consequence of active anabolism. If the anabolism occurs in a medium isotonic with normal extracellular fluid and is accompanied by little or no catabolism, water will be freed. This situation obtains in the mammalian foetus which, while showing little catabolic activity, is rapidly synthesizing the large molecules of its cell constituents from small molecules passing through the placenta into its circulation. The osmotic freeing of water by this process is sufficiently great to account for the hypotonicity of the foetal fluids and urine.

In making a rough calculation one may consider protein synthesis only. On the 23rd day of gestation the rabbit foetus contains 0.62 gm. protein and on the 27th day, 1.7 gm. protein³, so in this four-day period it has synthesized 1.08 gm. protein. If one assumes: (a) that mean weight of the protein molecules formed is about that of tropomyosin (mol. wt. 80,000; 670 amino-acid residues/mol.), and (b) that the amino-acids used in protein synthesis are presented to the foetal tissues as undissociated molecules in a solution of osmolar concentration 300 milliosmoles/l., one can calculate that during this four-day period of gestation 0.0135 millimole of 'tropomyosin' has been formed from 9.1 millimoles of amino-acids, which would be contained in 30.4 ml. of solution. The 'tropomyosin' thus formed (assuming that the cell contents are isotonic with extracellular fluid) would require only 0.05 ml. water for its solution. The synthesis has therefore set free 30.35 ml. water. Unless the placenta removes this volume of water in excess of solute, some

water will accumulate on the foetal side of the placenta and dilute the foetal fluids or urine. Strongly hypotonic allantoic fluid is in fact found in ungulates, the placenta of which is less permeable than that of rabbits⁴.

This rough calculation relates not, of course, to the absolute exchange of water between the maternal and foetal organism, which is known to be very large⁵, but simply to the osmotic freeing of water by the conversion of many small molecules into a few large ones. The synthesis of protein will also cause a comparatively small absolute increase in water by release of metabolic water in the formation of peptide bonds.

A similar process in actively growing young plants has been described by Lundgårdh⁶. Wheat seedlings grown in salt-free sugar solutions synthesize protein from the sugar together with nitrates already present in the plant; and during this process the tissue fluid (collected as bleeding sap from the cut end of the stem) becomes hypotonic, as a result of the 'extra water' released by the decrease in the number of molecules present. It is suggested that the hypotonicity of mammalian foetal fluids and urine may result from an analogous process.

I am indebted to several colleagues for helpful discussions of this point.

PATHOLOGY

Inhibition of Exogenous and Endogenous Pyrogens by Lysozyme

SINCE lysozyme has been used for therapeutic purposes it has been observed that a rapid fall of temperature may follow its administration. Experiments were, therefore, planned to find out if Fleming's bacteriolysin prevented the rise of temperature caused by exogenous and endogenous pyrogens in rabbits.

Subcutaneous injection of 400 mgm./kgm. of lysozyme were found to reduce to some extent the effects of the intravenous administration of an exogenous pyrogen (pyromen), whereas subcutaneous administration of similar amounts of gelatin did not. Since smaller doses of lysozyme had no effect, it was considered possible that the large doses were producing their effect by interacting with endogenous pyrogen which, as it is well known, is responsible for most of the rise of temperature observed after injecting exogenous pyrogens¹⁻³.

This assumption has been proved to be correct in experiments carried out by means of Bennet and Beeson's technique⁴. Rabbits were prepared by shaving the abdomen, and 350 c.c. of physiological saline containing 60 units of penicillin and 0.8 mgm. of streptomycin per c.c. was infused into the peritoneal cavity, slowly, so that the infusion was completed in 3 hr. The animals were kept on their backs for 4 hr. after termination of the injection. Then the abdomen was opened and all fluid in the peritoneal cavity was aspirated into sterile Erlenmeyer flasks.

Fig. 1

The peritoneal fluid, which was centrifuged until it was clear, produces the typical hyperthermia due to endogenous pyrogen if it is administered intravenously to rabbits (dose, 10 c.c. per 2-kgm. rabbit). If sterile lysozyme hydrochloride is dissolved in the saline solution to be infused into the abdominal cavity at a concentration of 0.5 mgm./c.c., then peritoneal fluid cleared by centrifugation does not produce hyperthermia, when it is injected intravenously into rabbits (dose, 10 c.c. per 2-kgm. rabbit).

In controls carried out with sterile gelatin, utilizing the same concentrations, the peritoneal fluid cleared by centrifugation can produce the hyperthermia characteristic of an endogenous pyrogen.

Measuring the fever curves with a planimeter, it is possible to determine the 'fever index' utilized by Beeson⁵. The antipyrogenic action of lysozyme is expressed graphically in Fig. 1, in which values of the 'fever index' are plotted as ordinates and values of lysozyme concentration as abscissae.

Effects of Hexamethonium Bromide and β -Amino Propionitrile on the Tensile Strength of the Aorta of Mice

Beaven and Murphy¹ suggested that the ganglion-blocking agents, hexamethonium bromide and pentolinium, might weaken the aortic media, because nine of a series of 44 hypertensive patients under treatment with these agents died suddenly from dissecting aneurysm of the aorta. Six of the nine fatal cases had malignant hypertension. Although in a large autopsy service we have observed this association only in one case of malignant hypertension treated with 'Darenthin', we decided to test the hypothesis by comparing the effects of hexamethonium bromide alone and in association with the lathyrus factor β -amino propionitrile on the static tensile strength of the aorta in normal mice. The latter compound is well known to weaken the aortic media in experimental animals by an antimaturant action on collagen².

White mice of both sexes aged 3-4 weeks were used in five successive experiments each comprising 60 animals. This age-group was chosen because Ponseti and Shepard³ found that the most marked aortic lesions were produced in the rat when treatment with a lathyrus diet was begun before the age of 4 weeks. Further, Gillman and Hathorn⁴ suggest that animals immediately after weaning should be used to assess the aortic effects of β -amino propionitrile because at this time aortic growth and remodelling are maximal.

In each experiment the 60 mice were divided at random into four groups of 15 animals. Each experiment lasted 3 weeks. Animals in group 1 received a single daily subcutaneous dose of 5 mgm. of β -amino propionitrile. Those in group 2 were given two doses daily each of 0.5 mgm. of hexamethonium bromide. This dose was determined after preliminary trials, which showed that a single dose of 1.5 mgm. caused rapid convulsive death and that 0.5 mgm. was the maximum dose which could be given over a period of 3 weeks without causing significant mortality. Group 3 received each day the combined regime of a single dose of 5 mgm. of β -amino propionitrile and two daily doses of 0.5 mgm. hexamethonium bromide. The β -amino propionitrile and the first dose of hexamethonium were given close together each morning and the second dose of hexamethonium each afternoon. Group 4 animals were uninjected controls.

At the end of the experimental period of 3 weeks the mice were killed in random order over a period of 3 days, during which no drugs were given. The thoracic aorta was carefully dissected free from fascia, suspended between clamps and weights added to the lower clamp until the aorta broke.

The breaking strain was found to vary considerably between animals treated alike. Results are shown in Table 1.

Table 1. BREAKING STRAIN (GM.) OF AORTIC MEDIA

	Control	β -Amino propionitrile alone	Hexamethonium alone	β -Amino propionitrile + hexamethonium	Experiment mean
Experiment 1	44.2	38.8	48.0	36.6	42.1
Experiment 2	47.6	44.7	42.7	35.8	42.8
Experiment 3	47.2	39.3	47.6	40.3	43.5
Experiment 4	44.3	37.3	38.4	38.3	39.5
Experiment 5	44.7	32.5	40.3	34.8	38.1
Treatment mean	45.7	38.7	43.4	37.2	40.5

The standard errors of the difference between individual treatment means was 1.94. It was therefore apparent that β -amino propionitrile produced a significant weakening of the aortic media, but that treatment with hexamethonium bromide did not do so, nor did it potentiate the weakening effect of β -amino propionitrile.

BIOLOGY

De novo Origin of the Nuclear Membrane

THE behaviour of the nuclear membrane in prophase and telophase is indeed one of the most attractive features of mitosis for the electron microscopist and cytologist¹. This was recently emphasized by Porter and Machado² in their review of the literature preceding their own electron microscope observations of mitotic onion root cells. In summary, the nuclear membrane or envelope is formed either by a coalescence of vesicles derived from the endoplasmic reticulum at the chromosome surface, or, as in the case of the onion cells, by slender lamellar units of the endoplasmic reticulum draping themselves around the chromosomes at the poles in telophase. Not one of these studies shed any light on the intriguing question posed by Bernhard³ regarding the possibility of a *de novo* origin for the nuclear membrane.

In a problem like this, the selection of proper research material is perhaps more important than formulation of the original proposition. In such material, the number of cells undergoing mitosis should be unusually high, and the cells should not contain much endoplasmic reticulum and relatively few mitochondria. Electron microscope studies for an entirely different problem revealed that foetal liver (human and rat) is an excellent tissue for a number of cytological problems⁴. At certain stages of development, the actively proliferating erythroblastic cells may outnumber the hepatic cells and even deform them by encroachment. In the youngest erythroblasts, fixed with buffered osmic acid, the sparse slender profiles of endoplasmic reticulum disappear gradually by fragmentation into small vesicles. Basophilic erythroblasts (normoblasts), which are characterized by an abundance of ribonucleoprotein particles and a small volume of endoplasmic reticulum or an involution of it^{5,6}, are mitotically quite active.

During prophase the nuclear membrane leaves the surface of the contracting chromatin, fragments and migrates towards the cell periphery. It is apparently metabolized after further fragmentation into vesicles. Although this lamellar structure may persist into the telophase stage, it is not related to the reconstitution of the new nuclear membrane.

Reconstitution of the nuclear membrane occurs first, multicentrically, around the periphery of the daughter cell chromosomal mass farthest away from the interzonal spindle fibres (Fig. 1). Examples of aberrant chromosomal masses and differential mitosis further emphasize that remnants of lamellar endoplasmic reticulum are not required for the formation of the nuclear membrane in erythroblasts.

This evidence for the *de novo* origin of the nuclear membrane assigns to the chromosomal mass a much more important role in its formation than has been possible in previous electron microscope studies because basophilic erythroblasts are remarkably free from lamellar and vesicular endoplasmic reticulum. This interpretation is in keeping with light microscope studies showing that the nuclear membrane is first formed in telophase by the coalescence of membranes from the cytoplasmic surface of each of the chromosomal vesicles⁷. Hence, the nuclear membrane stands in a direct genetic relation to the chromosomal parts⁸,

Fig. 1. Electron micrograph of a portion of the chromosomal (Ch) mass in telophase of an erythroblast from a 15-day rat fetal liver. Arrows indicate the reconstitution of the nuclear membrane. A remnant of the nuclear membrane from the preceding prophase nucleus is shown at R. A portion of a mitochondrion is in the upper left corner. ($\times 16,666$)

and in the case of basophilic erythroblasts, it would be actively involved in the nucleo-cytoplasmic exchange of basophilic material.

This investigation was supported by Grant No. Cy 3458 (C2) from the U.S. Public Health Service.

Auxin Control of Protein-Levels in Detached Autumn Leaves

It is well established that when mature leaves are detached from the plant the protein-level in the blade falls¹. It has also been demonstrated by both Vickery, Pucher, Wakeman and Leavenworth² and Mothes and Engelbrecht³ that an external supply of carbohydrate or of nitrogenous substances such as nitrates, ammonium salts or urea, will only slow down the rate of the protein degradation. If detached leaves are maintained in nitrogen, however, the fall in protein can be considerably retarded without the addition of metabolites⁴, while the reduction in

protein-level can be entirely suppressed under normal aerobic conditions once root initials have been formed on the petiole⁵. The retention of protein in detached but rooted leaves caused Chibnall⁵ to propose that a root factor, possibly hormonal in nature, is essential for the synthesis of protein in leaf tissue. In this connexion the findings of Richmond and Lang⁶ and Person, Samborski and Forsyth⁷ are of considerable interest. The former workers showed that when detached unrooted leaves of *Xanthium* were kept with their petioles in 5 or 10 mgm./l. kinetin the loss of protein was retarded, and the chlorophyll and green colour of the blade were maintained. Person *et al.*⁷ reported similar effects on detached wheat leaves floated on solutions of benzimidazole. Later, Mothes, Engelbrecht and Kulajewa⁸ elegantly demonstrated that when solutions of kinetin were applied locally to the surface of mature tobacco leaves the original levels of protein and chlorophyll were maintained in the treated areas; furthermore, nitrogenous compounds applied to other parts of the leaf moved towards the parts treated with kinetin. In a recent communication⁹, one of us directed attention to the importance of auxins in the control of physiological changes occurring during the autumn senescence of both attached and detached leaves. Local applications of the *n*-butyl ester of chlorinated phenoxyacetic acids to the surface of green autumnal leaves of cherry resulted in a retention of photosynthetically active chlorophyll and the conservation of alcohol-insoluble nitrogen in the treated areas. In contrast, untreated parts and control leaves became completely yellow and showed a greater reduction in the protein-level. These investigations have now been extended, and more detailed work has revealed that the total protein-levels in the auxin-treated areas of the leaf may be wholly maintained for periods of more than two weeks, during which time the total protein in control leaves and untreated parts of the treated leaf may fall to half the original values.

Fully green leaves were removed from trees of *Prunus serrulata* in late October. A drop (1.9 μ l.) of an ethanol solution of the *n*-butyl ester of 2,4-dichlorophenoxyacetic acid was applied to the upper surface of the lamina, on each side of the main vein, to give a total dose of 25 μ gm./spot (acid equivalent). Control leaves were treated with ethanol. The leaves were maintained in high humidity in an unheated greenhouse in normal day-length. The cut ends of the petioles dipped into beakers containing distilled water which was changed daily.

Within 6 days, control leaves and the untreated areas of the treated leaves began visibly to lose chlorophyll and turn yellow, and by the eleventh day, the areas treated with 2,4-dichlorophenoxyacetic acid remained as green islands of tissue in an otherwise yellow leaf. At appropriate intervals the levels of different nitrogen fractions were determined in disks of tissue, 1.5 cm. in diameter, cut from control leaves and from treated and untreated parts of the treated leaves. Determinations of total, 80 per cent ethanol-insoluble and 80 per cent ethanol-soluble fractions of nitrogen from duplicate samples of tissue were carried out by the usual micro-Kjeldahl techniques. After correcting for the small changes that occurred in the fresh weight of the leaf and hence in the leaf area it could be shown that there was no change in the total nitrogen value for the different areas of the blade. Results are therefore expressed as the ratio of 80 per cent ethanol-insoluble nitrogen

Fig. 1. Ratio of 80 per cent ethanol-insoluble nitrogen/total nitrogen in control leaves and in areas treated and untreated with 2,4-dichlorophenoxyacetic acid in blades of detached autumn leaves of *Prunus serrulata*. The departure from the mean for each individual point varies from 0.6-5 per cent

to total nitrogen. This measure of protein nitrogen within the tissues at different times after treatment is shown in Fig. 1. It is clear that while nearly 50 per cent of the protein is degraded in control and untreated areas the protein-level is maintained in the tissues treated with 2,4-dichlorophenoxyacetic acid. Further estimations have shown that in the control and untreated tissue, there is an increase in α -amino, amide and ammonia nitrogen corresponding to the decrease in protein.

Treatment of detached cherry leaves with 2,4-dichlorophenoxyacetic acid labelled with carbon-14 in the carboxyl group, followed by detection of carbon-14 by autoradiography, showed that the labelled carbon is retained entirely within the areas of tissue which remain green. It was also found that neither the continuous supply to the petioles of an aqueous solution of kinetin at 25 mgm./l. nor a local daily aqueous spray of kinetin at 100 mgm./l. was effective in delaying protein degradation or preventing yellowing of the blade. Indole-3-acetic acid was equally ineffective, but spot applications of indole-3-aceto-nitrile produced visible responses similar to those described for 2,4-dichlorophenoxyacetic acid.

Respiratory measurements on leaf disks from control leaves or from untreated areas of leaves treated with 2,4-dichlorophenoxyacetic acid revealed a similar and continuing increase in oxygen-uptake starting after detachment from the tree and reaching a peak some ten days later. Concomitant with this increase in oxygen consumption there was a rapid fall in protein-level and a loss of chlorophyll. This phase was followed by a continuous decline in oxygen consumption corresponding to the further slow decrease in protein-level. In the areas treated with 2,4-dichlorophenoxyacetic acid the period of increasing oxygen consumption was postponed by some twenty days from the time of detachment and treatment, and, as with the control and untreated areas, the peak of oxygen-uptake again corresponded with the period of rapid protein degradation. By the end of the experiment (24 days) the tissues in the treated areas were still light green and capable of fixing labelled carbon dioxide in the light. At no stage was there any visible indication that root

formation, cell division or other morphological change had occurred in the treated leaves.

Since the areas which remain green are the only ones in which carbon-14 can be detected after treatment with carbon-14 labelled 2,4-dichlorophenoxyacetic acid, and since the retention of chlorophyll and protein is restricted to these areas, it must be concluded that these effects on chlorophyll and protein are due to a direct effect of treatment with 2,4-dichlorophenoxyacetic acid. In both the yellowing control leaves and the untreated parts of the treated leaves it is clear that degradation of protein must exceed synthesis.

A number of postulates can be advanced to explain the ways in which 2,4-dichlorophenoxyacetic acid may control the protein-levels in these senescing leaves.

(1) The retention of actively photosynthetic chlorophyll might lead to a sparing of protein by increasing the supply of carbohydrates. However, Vickery, Pucher, Wakeman and Leavenworth¹⁰ have shown that active photosynthesis and even accumulation of carbohydrate in mature detached tobacco leaves does not, in fact, retard protein breakdown. It is improbable, therefore, that the effect of 2,4-dichlorophenoxyacetic acid can be accounted for in terms of increased carbon substrates.

(2) Racusen and Aronoff¹¹ showed that in soya bean leaves the incorporation of labelled carbon dioxide into the amino-acids of protein decreased with increasing time after detachment from the plant. It may be, therefore, that 2,4-dichlorophenoxyacetic acid acts by preventing a decline in the rate of incorporation of amino-acids.

(3) It is also possible that protein turnover is completely blocked by treatment with 2,4-dichlorophenoxyacetic acid, so that neither synthesis nor degradation occurs.

Many metabolic processes have now been shown to be correlated with the hormone status of the plant. The evidence presented here suggests that auxins are controlling factors in certain pathways of protein metabolism.

We wish to thank Mr. R. G. Powell for his assistance and Prof. G. E. Blackman for his encouragement.

Influence of Light from an Infra-red Bulb on the Mutagenic Effect of Colchicine on Sorghum

TRUE-BREEDING diploid mutants have been found to arise from colchicine-treated *Sorghum* seedlings of the true-breeding lines, Experimental 1 and Experimental 3¹⁻⁵. Their true-breeding nature is similar to that obtained after many generations of selfing so that they appear to be immediately homozygous for the new characteristics. Some non-true-breeding mutants also occur. It was proposed that the true-breeding condition might arise by a somatic reductional division of the chromosomes, similar to that observed by Huskins⁶, with subsequent restoration to the diploid number, and that the mutant condition might arise through concentration of chromatin from one of the original ancestors from which Experimental 3 had been derived. However, from cytogenetic studies of hybrids between true-breeding mutants and their untreated full sibs, the genetic changes appear to be due to gene mutations^{4,7-9}. Tests of the somatic reduction hypothesis using chromosome markers (recessive genes and reciprocal translocations) in the heterozygous condition in sorghum and other materials have not been decisive^{1,7,10} except for one case in flax (gene markers) which indicated its seeming validity¹¹.

The definition of a laboratory method for the production of true-breeding mutants after colchicine treatment has been found to be of paramount importance from the point of view of testing the hypothesis of somatic reduction since variable success results under greenhouse conditions. For this purpose the influences of environmental factors on the induction of mutants are being determined. Recent investigations involving more than 1,000 colchicine-treated seedlings have been carried out using aseptic cultures kept under light and temperature conditions with various degrees of control¹². Only four mutated plants, none true-breeding, were obtained. The problem, therefore, was to identify the particular factors responsible for the difference in results between sand jars in the greenhouse, which had given as high as 42 per cent true-breeding mutants², and aseptic

cultures under light and temperature conditions controlled to varying degrees, which gave very few mutants, none true-breeding. Light was a possible factor since most of the seedlings in aseptic culture were grown in a box with artificial light, or in the laboratory, or under shades in the greenhouse, while those in sand jars were grown in the greenhouse without shades. Infra-red light was investigated since these rays penetrate glass, have been found to modify chromatin re-arrangements induced in *Drosophila*¹³ and in *Tradescantia*¹⁴, and have been shown to play an active part in the control of many aspects of growth and differentiation¹⁵.

In experiments in Table 1, untreated and treated seedlings of line Experimental 3 were grown in glass-covered jars on sand with tap-water and in test-tubes on agar both with full nutrient and with distilled water. Treatment consisted of application of 0.5 per cent colchicine in lanolin to the coleoptiles immediately after germination. Comparisons were made between shaded and unshaded conditions in the greenhouse and continuous illumination from a 'Heat Ray' bulb (infra-red, 250 W.) at approximately 78° F. for seven days immediately after treatment. Progeny tests were made of surviving plants from these experiments.

Light conditions and medium influenced both survival of treated seedlings and induction of mutants. Infra-red light cannot be considered the only factor precipitating the appearance of true-breeding mutants since changing the culture from sand to agar prevented their induction. It may be of importance that mutants appeared only under conditions which gave high mortality. This observation agrees with previous findings that although agar with or without nutrients increased survival of treated seedlings over that in sand jars, the number of mutants induced by colchicine treatment is decreased by this and other improved growing conditions¹². The high rate of mortality associated with the induction of true-breeding diploid mutants suggests that the balance between stress conditions causing death and those causing origin of a mutated shoot, which displaces

Table 1. INCIDENCE OF TRUE-BREEDING DIPLOID MUTANTS AND POLYPLOID PLANTS, AS INDICATED BY PHENOTYPE AND VERIFIED BY PROGENY TESTS, FROM UNTREATED AND COLCHICINE-TREATED SORGHUM SEEDLINGS (LINE EXPERIMENTAL 3) WITH DIFFERENT ILLUMINATION AND MEDIA

original tissues, is delicate and subject to many factors difficult to control.

The true-breeding diploid mutants which arose after infra-red illumination were similar to those obtained previously from treated seedlings grown in an unshaded greenhouse. Both groups exhibited obvious changes in height, leaf, midrib, panicle, glumes, awns and seed colour, and bred true immediately. These results provide a clue to the variability in occurrence of mutants in greenhouse experiments since light conditions change with the amount of sunshine. They are particularly significant since it is indicated that the phenomenon of the induction of true-breeding mutants can be produced under laboratory conditions. There are therefore external conditions such as light, medium and temperature which determine the occurrence of this phenomenon as well as internal conditions determined by the genotype as indicated by Atkinson *et al.*².

Induction of true-breeding mutant types by colchicine treatment of germinating seedlings in the greenhouse has been used with great success in the sorghum-breeding programme at South Dakota State College both to secure new variability and to obtain fixed genotypes immediately. The significance of this phenomenon for currently held theories regarding the behaviour of chromosomes within somatic tissues would seem to be far-reaching, particularly in our understanding of growth processes and, perhaps, of the origin of abnormal growths such as cancer.

Changes in Amounts of Organic Acids in Citrus Leaves during Periods of Cold Storage

STORAGE of certain plant products at temperatures below 15° C. but above freezing can cause severe injury to their tissues. As one mechanism to explain this, it has been suggested that cold temperatures could cause changes in the rates of metabolic reactions which would result in an increase or decrease in amounts of metabolic intermediates¹. Such changes, when excessive, could directly or indirectly damage the plant cells.

Storage at cold temperatures has been shown to cause increases in the respiratory rate of citrus fruit², leaves (Eaks, Irving L., personal communication, 1960), and other plant materials^{3,4} both before and after the breaking point for the onset of injury. The earliest measured response of sweet potatoes to the chilling temperatures was an accelerated respiratory rate⁴, even though at this time no injury had resulted.

Biochemical studies on sweet potatoes indicated that changes in mitochondrial activity could not explain the increased respiratory rate of tissues which had been stored at low temperatures⁵. There is a possibility that changes in amounts of organic acids caused by the periods of cold storage could explain such respiratory increases. The amounts of a number of organic acids in citrus leaves were determined, therefore, to see if any changes occurred and if these changes were associated with cold injury.

Three lemon plants (Lisbon variety, 3 months old) were placed in a darkened chamber at 1° C. An identical number of plants were introduced into darkened chambers at 10° C. and 20° C. A continuous stream of air, saturated with water vapour, was passed through each chamber so that one exchange of air occurred approximately every 15 min. After a predetermined storage period the plants were removed. The third fully expanded leaf from the growing point was removed from each plant. The plants were then placed in a greenhouse, and after 48 hr. the leaf damage resulting from the cold-temperature storage on the unexcised leaves was recorded. Each leaf which was removed was weighed and ground in a pestle and mortar with quartz sand and 3.0 ml. of distilled water. After centrifugation, one aliquot of this solution was titrated to a phenolphthalein end-point with standard sodium hydroxide. The results obtained from this titration were used to determine the total acidity present. Another measured aliquot (usually 1.5 ml.) was mixed with 0.05 ml. of 36 N sulphuric acid and 1.5 gm. of silicic acid. The free-flowing powder was quantitatively transferred to a previously prepared silica-gel column. The method of Bulen *et al.*⁶ was used for the determination of the acids present. Each determination, therefore, gave the acids present in a single leaf. This procedure was repeated on identical groups of plants stored for varying periods of time at the different temperatures.

The results in Table 1 indicate that cold storage caused as much as a 140 per cent increase in amount

Table 1. CHANGES RESULTING FROM COLD TEMPERATURE STORAGE IN AMOUNTS OF ORGANIC ACIDS IN CITRUS LEAVES*

Organic acid	Normal level	Change due to cold storage	
	2 weeks at 20° C. μ equiv./gm. of leaf	2 weeks at 1° C. Δμ equiv./gm.	2 weeks at 10° C. Δμ equiv./gm.
Unknown	23	- 3	- 3
Acetic	4	- 2	0
Fumaric			
and formic	48	- 7	- 7
Succinic	5	+ 4	+ 6
Malonic	6	+ 1	+ 2
Oxalic	81	-13	-17
Glycolic	82	-25†	-19
Malic	59	+62†	+83†
Citric	280	-88†	-98†
Isocitric	73	+14	+ 8

* Each value is the average obtained from six different leaves. Gain of acid over 20° control is indicated by plus values, loss by negative values.

† Significantly different from the amount of the same acid found in the 20° C. sample at the 5 per cent probability-level.

of malic acid in the leaf tissue and a 35 per cent decrease in amount of citric acid. In one case not shown there was a 170 per cent increase in malic acid and a 77 per cent decrease in citric acid. Similar results were obtained in all the experiments conducted. It should be noted that the greatest part of the changes produced by the cold storage occurred between 20° C. and 10° C.

A comparison of the total free acids present in the leaf tissue stored at the lower temperature with those at 20° C. revealed that essentially no significant change had occurred even though malic acid and possibly isocitric acid were accumulated.

These results suggest that the ratio of the individual acids to each other was important in the development of cold injury. It is not inconceivable that the accumulation of malic acid and loss of citric acid was in some direct way related to the stimulation of respiration which has been reported and perhaps to the primary damaging reactions producing the injury.

In this type of work it is important to differentiate between those changes which are the result of the death of the cells and those primary changes which cause the death of the cells. Since a redistribution of organic acids occurred both before and after the breaking point for the onset of leaf injury, the organic acid changes reported here could have been closely associated with the primary cause of cold-temperature injury.

Morphological Reactions of Germinating Seeds as Criteria for the Plant Growth Regulating Activity of Auxin-Type Chemicals

STUDYING the plant growth regulating effects of more than one hundred chemicals, we directed our attention to the following problems, closely related to the mode of action of auxins: (1) Is there only one, common, basic (auxin-) reaction, underlying the diversity of 'auxin-like' growth effects? (2) Do higher plant species differ with regard to their relative sensitivity towards different auxins? (3) Is the physiological activity of potential auxin precursors to be simply explained by the conversion of the inactive precursor to the active auxin? (4) How far can species differences in the enzymatic conversion of auxin precursor to auxin explain the differences between their sensitivity to the application of auxin precursors? None of these questions has been so far answered¹⁻⁶.

With the above considerations in mind, our attention was directed to the wide range of different abnormalities in seedling development, caused by treating germinating seeds with 2,4-dichlorophenoxy acetic acid. The gross morphological effects of this compound were found to consist mainly of inhibition of growth in length on one hand, and stimulation of growth by abnormal cell proliferation

Fig. 1. The gross morphological effects of different concentrations of 2,4-dichlorophenoxy acetic acid on 6-day-old cucumber seedlings. C, untreated control, 5.5 to 1.0; the negative logarithm of the 2,4-dichlorophenoxy acetic acid concentration, with 1.0 equal to 1,000 p.p.m.

on the other hand, in the different tissues of the seedlings. The development of the diverse growth effects has shown strikingly high correlation. By comparing the gross morphological effects on cucumber seedlings of an unknown concentration of 2,4-dichlorophenoxy acetic acid to a series of reference standards, the logarithm of the concentration in the experimental Petri dish was found to be determinable within the concentration-range 0.03–1,000 p.p.m. with an accuracy of ± 0.25 (Fig. 1). Determination of concentrations of 2,4-dichlorophenoxy acetic acid was found to be possible using the same method with seedlings of any other species, although the great sensitivity obtained with cucumber seedlings could be achieved with other species generally only in a narrower range of concentrations of 2,4-dichlorophenoxy acetic acid.

The method, as applied by us in typical experiments, might briefly be described as follows: Three disks of filter paper were placed in Petri dishes and moistened with aqueous solutions of 0.1, 1, 10, 100, and 1,000 p.p.m., respectively, of the substance to be studied. Dry seeds of 23 species of crop plants were placed in a series of dishes (20 seeds of one species per dish, giving the above series of concentrations with every species), and incubated at 24° C. in the dark. The effects were evaluated on the sixth day, by comparing the morphological effects of every concentration with photographs (supplemented by detailed morphological descriptions) of the effects of a comparable series of concentrations of the reference substance(s) on the same species. Activity of a given concentration was expressed by that concentration of the reference substance which proved to be equally effective. In case the equal effectivity at any concentration of the reference substance seemed to be doubtful (due, for example, to a changed correlation between some of the observed growth effects) the disagreement with the reference substance was described and the seedlings photographed. Experiments were repeated at least three times; the results were found to be highly reproducible, in different seasons, and with seeds harvested in different years.

Our test as described above is opposed to the accepted auxin tests, in which statistically evaluated exact measurements of but one aspect (preferably growth in length) of the observable effects are involved while the others are neglected. The overall morphological effect is considered by us as a whole instead,

and used for the determination of equal effectivity with the standards. Fig. 1, nevertheless, illustrates convincingly that the evaluation of the results of the described 'phototest', within the limits of sensitivity given above, is free of subjective errors, and that the sensitivity of the method is comparable to any other biological auxin test. The visually perceptible great sensitivity of germinating seeds to different concentrations of the same auxin-type chemical is caused by strict correlations existing among a great variety of induced growth phenomena which, as a whole, are unmistakably characteristic for a narrow range of concentrations of the substance given. Differences, on the other hand, in the correlations between the observed growth effects, induced by different auxin-type substances, might yield much useful information about problems 1 and 3. In addition, the method presented is a laboratory test, highly reproducible, and reducing the importance of such secondary factors as uptake and transport, for studying possible differences in the sensitivity of different species to auxins as well as to auxin precursors. These characteristics of the method enabled us to draw some tentative conclusions concerning the problems summarized in the introduction, to be described in detail in further communications under preparation.

Transduction in Actinomycetes

GENETIC transduction has been demonstrated in a limited number of bacterial species, such as *Salmonella*, *Escherichia coli*, *Shigella* and *Pseudomonas aeruginosa*¹⁻⁴.

As regards Actinomycetes, we⁵ have shown that the donor culture on which the actinophage developed

determined the pattern of the recipient variation, induced by this actinophage. The ability of actinophage to transfer the prototrophic property from the wild-type strain to the auxotrophic one was also shown. Later, we attempted to obtain prototrophic colonies from an auxotrophic strain, treated with an actinophage, grown on another auxotrophic strain. In this case it was necessary that the donor auxotroph should differ in its nutrient requirements from the recipient auxotroph.

In our experiments, auxotrophic strains No. 2 (*Cys-His*⁺), No. 74 (*Met-His*⁺), and No. 80 (*Met-His*⁻), obtained after the treatment of *Act. olivaceus* strain N-6 with X-rays, were used. The transduction was carried out with a temperate phage No. 1. Three different combinations of the above auxotrophs were used. In the first combination, strain *His⁺Met⁻* (74) was used as the donor and strain *His⁺Met⁺* (80) as the recipient. Strain *His⁺Met⁺* (80), treated with a phage, grown on the same strain, and the culture of strain *His⁺Met⁺* (80), not treated with phage, were used as the controls.

In the second combination, strain *His⁺Met⁺* (80) was used as the donor and strain *Met-His⁺* (74) as the recipient.

In the third combination strain *Cys⁺His⁻* (80) was used as the donor and strain *Cys-His⁺* (2) as the recipient. The controls in the second and the third combinations was carried out in the same manner as in the first combination.

When corresponding phagolysates were plated on the minimal medium, it was observed that combinations *His⁺Met⁻* (74) × *His⁺Met⁺* (80), *His⁺Met⁺* (80) × *His⁺Met⁻* (74) and *His⁺Cys⁺* (80) × *His⁺Cys⁻* (2) very rarely produced prototrophic colonies similar to the wild-type colony (approximately 0.1 per cent). At the same time many small, compact and asporogenic colonies were detected on the Petri dishes. Such colonies were studied by transferring single isolates to the minimal agarized medium in tubes. The majority of them appeared to be auxotrophic with nutrient deficiency of the recipient. In addition, prototrophic colonies, characterized by distinct sporulation when grown on the minimal medium, were observed among them.

In the control combinations *His⁺Met⁺* (80) × *His⁺Met⁺* (80), *His⁺Met⁻* (74) × *His⁺Met⁻* (74), and *His⁺Cys⁻* (2) × *His⁺Cys⁻* (2) small asporogenic

Table 1. EMERGENCE OF PROTOTROPHS FROM AUXOTROPHS, TREATED WITH ACTINOPHAGE, GROWN ON AUXOTROPHS DIFFERING BY THEIR NUTRIENT REQUIREMENTS FROM THE RECIPIENT

Table 2. PLATINGS OF PROTOTROPHIC COLONIES, GROWN AS A RESULT OF TRANSDUCTION

Plating of prototrophic colonies grown from the following combinations	Colony type (per cent)			
	Prototrophic colonies	Recipient type colonies	Donor type colonies	Colonies with double nutrient deficiency
<i>His⁺Met⁻</i> (74) × <i>His⁺Met⁺</i> (80)	21.4	42.8	23.8	11.9
<i>His⁺Met⁺</i> (80) × <i>His⁺Met⁻</i> (74)	4.0	14.0	66.0	16.0
<i>Cys⁺His⁻</i> (80) × <i>Cys⁺His⁺</i> (2)	18.9	20.7	46.6	13.8

colonies were also observed. The analysis of these colonies did not reveal any prototroph among them. All these colonies appeared to be auxotrophs of the recipient type. No prototrophic colonies were detected among the many colonies obtained from auxotrophs No. 2, No. 74 and No. 80, not treated with actinophage.

The results of these experiments are presented in Table 1.

Two types of prototrophic colonies were shown to emerge from the platings of phagolysates. The first type, observed in all three combinations, formed only prototrophic colonies. Examination of the subsequent generations of these prototrophs showed the stability of the prototrophic property. The second type of the prototrophs, also observed in all the combinations studied, segregated out four colony types, that is, prototrophic colonies, auxotrophic colonies with nutrient deficiency of the donor, auxotrophic colonies of the recipient type and auxotrophic colonies with double nutrient deficiency, that is, with nutrient deficiency of both the donor and the recipient (Table 2). The subsequent generations of the four variant types isolated from the platings of the prototrophic colonies were studied. Some variants continued to segregate out colonies of the four types, others segregated out only two or one type of the colonies. However, after one or two transfers, non-segregating and stable lines of all four types were obtained.

How can we explain the segregation of all these forms out of prototrophic colonies, obtained as a result of transduction? If the prototrophs obtained are considered as hybrids, then the segregation of auxotrophs with nutrient requirements of the recipient is the segregation of the parent forms, while the segregation of auxotrophs belonging to the donor type, auxotrophs with double nutrient requirements, and prototrophs appearing stable through further generations are the result of recombinations similar to those induced by transduction in bacteria⁴⁻⁸. As for Actinomycetes, it is likely that a definite region of the chromosome appears to be in the 'diploid' state. The fact that on subsequent transfers the variants studied continue to segregate colonies with different nutrient deficiencies may be explained either by presence of different nuclei in the spores, or persistence of the nuclear 'diploid' state through several cell generations. It should also be pointed out that segregation of the donor-type auxotrophs and auxotrophs with double nutrient deficiency out of the prototrophic colonies may be the result of simultaneous transference by the actinophage of two factors, the normal allele of the biochemical deficiency of the recipient and the gene of the biochemical deficiency of the donor.

Transformation of a Strain of *Rhizobium lupini*

Transfer of Cysteine-independence. Strain H-13, which is a cysteine-dependent mutant of the prototroph *Rhizobium lupini* strain H, developed cysteine-independent colonies on treatment with the deoxyribonucleic acid of strain H (Fig. 1).

Fig. 1. (a) Transformed cysteine-independent colonies on minimal agar; (b) untreated control.

The small colonies are altered small-step reversions to prototrophy. 10^2 plated cells

The deoxyribonucleic acid was prepared by lysis with sodium deoxycholate (1 per cent) at 55° C. for 10-15 min., followed by deproteinization by Sevag's method and precipitation by 3 vol. ethanol. The transformation was accomplished in a basal salt medium containing cysteine and glucose, on cells pre-incubated for 24 hr.

Fig. 2 shows a typical experiment. In general, I varied the time of addition and action of deoxyribonucleic acid, its concentration, and also the concentration of the cells and the growth-limit, the latter by decreasing the concentration of cysteine.

The following observations were made concerning the mechanism of transformation: (1) at least three

Fig. 2. ●, Time of addition of deoxyribonucleic acid (0.15 µgm./ml.); ↑, time of plating on minimal agar.

Number of transformed colonies: (A) plating after 10 hr., 23; 24 hr., 86. (B) plating after 10 hr., 15; 24 hr., 24

Fig. 3. From left to right: nodule formation of *H*-13 after one transformation; *H*-13 after two transformations; *M*-32 (control). Plants 4 weeks old

cell divisions are necessary to bring about transformation; (2) the phenotypic expression of transformed cells is preceded by a long transformational lag, during which there is apparently no need for cell division and the transformed character is not yet multiplying.

In consequence of the rather low frequency of transformants—generally the numbers attained did not exceed those given in Fig. 2—the system was not appropriate for more detailed investigations of the mechanism. Probably it is the mucous consistency of strain *H*-13 which opposes the penetration of deoxyribonucleic acid; although it is possible that the medium employed may not have been optimal. Experiments now in progress with rough strains rather point to the first assumption.

Change of Host-specificity. It was proved by Nutman¹ that the relation of *Rhizobium* to the host plant is genetically determined by the plant. On the other hand, interspecific transformations carried out with several species of *Rhizobium*² show that the host specificity also is genetically controlled by the bacteria.

In the following experiments the cysteine-dependent *Rh. lupini* (strain *H*-13) was transformed by the deoxyribonucleic acid of an *Rh. meliloti* strain (*M*-32). Lucerne plants inoculated *in vitro* with *M*₃₂ form root-nodules on 95–100 per cent of the plants, whereas lucerne plants inoculated with *H*-13 form no nodules at all.

Preparation of *M*₃₂ deoxyribonucleic acid and transformation of strain *H*-13 were carried out as described above.

In a series of plants inoculated with deoxyribonucleic acid-treated *H*-13, out of 120 plants 14 (11.7 per cent) formed nodules. Generally these were atypical structures developing late; only three plants formed rather typical nodules of greater size. Nitrogen fixation did not occur anywhere. In some series inoculated with single colonies isolated from these nodules, a somewhat higher number of mostly belated ineffective nodules were formed.

The percentage yield did not change when cells of isolated colonies were newly transformed with the deoxyribonucleic acid of *M*₃₂; however, one part of the nodules formed developed at the same time as in the controls inoculated with *M*₃₂ and proved to be typical and later to be effective (see Fig. 3).

These observations suggest that two or more successive distinct transformation types are needed to produce the new host-specificity.

H-13 exhibited in an intraspecific system a low transformation frequency (see above), so in this interspecific combination we suppose the frequency to be essentially lower still, and the changed character as being detected only by the strong selective power of nodule formation.

CYTOLOGY

Mammalian Cell Chromosome Counts : a Simple Method for making Preparations

FOR those who work with small mammals, it is sometimes desirable to determine the chromosome complement in cells of particular individuals. Until recently, the most reliable technique for chromosome number determinations depended on the reasonably high mitotic rate and other desirable properties of the seminiferous tubules (for example, Matthey¹). The difficulty with those techniques is that they do not permit the assessment of chromosome numbers in females, or in males apart from during the breeding season. Beatty² described a method of preparing corneal epithelial cells for chromosome counts, which overcame the shortcomings of relying on testicular cells, but many of the metaphase plates were not adequately spread. As a consequence, chromosome counts of only 20 cells from a total of 445 could be listed as exact counts. More recently, Ford *et al.*³, and many other workers, have described very elegant techniques for mammalian chromosome counts, employing short-time culture of cells from a variety of tissues, primarily bone marrow. The primary difficulty with these techniques is the fact that very few laboratories have the equipment or personnel necessary for the carrying out of tissue culture. Another difficulty is the apparently large number of cells which possess chromosome numbers different from the diploid number. One cannot be sure if this heteroploidy is present in the tissue in the live animals or arises as a result of the extensive preparatory technique. This communication sets forth a relatively simple method for preparing corneal epithelium cells for reliable chromosome counts.

The animal, the cells of which are to be examined, is injected intraperitoneally with 0.01 ml. of 0.04 per cent aqueous colchicine solution/gm. of body-weight. After 3–4 hr. the animal is killed, the eyes are cut out and placed in 0.3 per cent sodium chloride at 37° C. for ½ hr. Fixation takes place in aceto-carmine overnight. Pieces of the epithelial layer are

Fig. 1. Metaphase chromosomes of male *Mus musculus*Fig. 2. Metaphase chromosomes of *Apodemus sylvaticus*

scraped from the cornea into a drop of aceto-carmin on an albuminized slide. The drop is then covered with a piece of 'Cellophane', a $\frac{3}{4}$ -in. square cover-slip and filter paper, and the tissue is squashed in a press, delivering a pressure of about 40 kgm./sq. cm. of cover-slip (see Beatty² for details of the press). The 'Cellophane' is removed by letting the slide stand in tap water for about 5 min. Slides are then stained by the standard Feulgen procedure. Hydrolysis is for 10 min. in N hydrochloric acid at 60° C.

Preparations made this way from *Mus musculus*, *Apodemus sylvaticus*, and *Clethrionomys* sp. have invariably yielded many clear, well-spread metaphase plates, excellently suited to chromosome counting. As many as 30 metaphase plates suitable for counting are available from the epithelium of one mouse cornea. Typical plates are shown in Fig. 1 for the mouse and Fig. 2 for *Apodemus*.

In order to assess the efficacy of this method, the chromosomes of 5 cells from each of 10 male and 10 female mice were counted. The first 5 cells to appear suitable during examination with a low-power microscope objective were counted. The results are shown in Table 1. Of the 100 cells counted, an exact count was possible in 77, that is, there was no overlapping or crowding of the chromosomes so that no doubt existed about the precision of the count. Of these 77 cells, all but one contained 40 chromosomes. This one contained only 36. In 23 cells there were one or two places where mistakes might have occurred in counting, and these were therefore

Table 1. NUMBERS OF CELLS CONTAINING VARIOUS CHROMOSOME NUMBERS

	Chromosome count				
	36	40	40 ± 1	40 ± 2	44 ± 2
Males		35	11	4	
Females	1	41	5	2	1
Total	1	76	16	6	1
					100

not scored as exact counts. Nevertheless, in 22 of these 23 cells, the 'most likely' number of chromosomes was 40. In one cell the 'most likely' number was 44. If one combines the exact counts and the 'most likely number' counts, it is seen that 98 of 100 cells have chromosome numbers compatible with the number 40. This confirms the observation of Beatty that the corneal epithelium exhibits extremely high constancy in regard to chromosome number. The apparent advantage of the method described here over that described by Beatty is in the much greater proportion of cells the chromosome number of which could be exactly determined. When compared to the techniques involving tissue culture, my method enjoys the advantages of simplicity and constancy of chromosome number, but suffers the disadvantage that the animal must be killed. Because the corneal epithelium is a surface tissue and because both chromatids of each chromosome are clearly visible in the cells prepared by this technique, it would appear that this might be an excellent means of ascertaining the extent of chromosome breakage in the living animals which is caused by ionizing radiation or other agents.

This work was done during the tenure of a Nato postdoctoral fellowship. I would like to express gratitude to Prof. C. H. Waddington for permission to work at the Institute of Animal Genetics and for providing space and facilities; to Dr. J. G. Campbell for taking the photographs; and to Dr. R. A. Beatty for continual helpful advice, and for collecting the wild rodents.

Structural Changes in Mitochondria of *Acanthamoeba* at Encystation

FOR some time now the mitochondria have been ascribed a role in cellular respiration and more recently changes in intracellular ion concentration and tonicity have been shown to have marked effects on both mitochondrial volume and respiratory activity¹. This communication reports changes in the structure of the mitochondria of a small amoeba occurring at a time in the life-cycle when the intracellular environment is undergoing profound changes and respiratory activity is reduced to a minimum, namely, at encystation.

A clone strain of a soil amoeba, *Acanthamoeba* sp., was isolated in this laboratory and maintained in monoxenic culture with *Aerobacter aerogenes* on 0.2 per cent peptone agar plates. The organisms were washed off the plates with distilled water before

Fig. 1. Part of section of cyst showing three mitochondria with intra-cristal vesicles (icv), also tubules of endoplasmic reticulum (er)

fixing in permanganate² at pH 7.2 for 2 hr. at 4° C. Dehydration was in ethanol, 'staining' in 1 per cent phosphotungstic acid in absolute ethanol and embedding in 'Araldite'. Silver or gold sections were cut on the Porter-Blum microtome, mounted on carbon films and examined in the Siemen's Elmicope 1b electron microscope.

The mitochondria of trophic amoebae are usually oval in shape and measure $0.5-1.5\mu \times 0.5-1.0\mu$, but the shape is variable, and cup-shaped and even branched mitochondria have been seen in sections. Their internal structure resembles that of other free-living Protozoa. Each is surrounded by a double membrane: from the inner membrane tubular cristae project into the mitochondrial lumen and in some cases they can be seen to traverse it. Often small spherical inclusions can be seen inside the cristae. These have a diameter of 500–1000 Å. and if not completely electron-dense have a thick electron-dense cortex. More than one of these intra-cristal inclusions has never been observed in a mitochondrion.

In the mitochondria of the cyst the intra-cristal inclusions take the form of larger vesicular structures. They have a diameter of 3000–5000 Å. ($0.3-0.5\mu$) and they are more opaque to the electron beam than is the surrounding mitochondrial matrix (Fig. 1). Electron-dense granules, irregular in size (50–300 Å.) and shape, lie immediately beneath the bounding membrane of the vesicle. The mitochondria of the cyst are usually spherical, $0.5-1.0\mu$ in diameter. In

some sections of cysts the outer membrane of a mitochondrion appears to be continuous with the membrane of a tubule of the endoplasmic reticulum.

It appears that at encystation in *Acanthamoeba* the intra-cristal bodies of the mitochondria swell to become vesicles which occupy a considerable part of the mitochondrial lumen. This change is represented in diagrammatic form in Fig. 2. One effect of this swelling is presumably to reduce the volume of the mitochondrial lumen. In a recent experimental study of the osmotic properties of isolated *Acanthamoeba* mitochondria, Klein and Neff¹ found that respiratory-rate was proportional to mitochondrial volume and that both were decreased by raising the tonicity of the surrounding medium. They suggested, however, that mitochondrial volume changes were under most conditions not primarily due to osmotic effects but rather to colloid swelling and shrinking phenomena. The effects of experimental changes in tonicity on the intra-cristal inclusions of *Acanthamoeba* have not yet been studied. A fuller report of work on the fine structure of this and other *limax* amoebae will be published elsewhere.

I wish to thank Prof. J. Z. Young for facilities in his electron microscope laboratory and Dr. J. D. Robertson for his interest and advice.

BACTERIOLOGY

Heterogeneity of Cultures of *Escherichia coli* B/r

A LARGE amount of the recent literature in radiation bacteriology and allied fields is concerned with the detailed behaviour of cultures labelled *Escherichia coli* B and *Escherichia coli* B/r. *E. coli* B is a bacterial strain that has been maintained for many years, mainly in laboratories concerned with bacteriophage synthesis and behaviour. It is characterized by its unusual sensitivity to several deleterious agents, including the T series of coli bacteriophages. *E. coli* B/r is one of a large group of mutants selected from *E. coli* B after irradiation with ultra-violet light. Within carefully defined B/r and distinguished it from B and other ultra-violet-selected mutants of B^{1,2}. *E. coli* B/r was characterized by, among other things, its enhanced resistance to ultra-violet light, X-rays, penicillin, and sodium sulphathiazole. Furthermore, the snake-like forms found with very high frequency in B cultures irradiated with ultra-violet were found only occasionally in B/r.

A survey of the literature and our own experimental experience suggest that the various cultures labelled *E. coli* B/r are not identical. For example, Morse and Carter³ claimed that B/r had 3–4 times more deoxyribonucleic acid per cell than B, whereas Harold and Ziporin⁴ claimed that there was no difference. Preliminary results obtained in this Laboratory suggested that the viable cell titres and X-ray sensitivities of two B/r cultures being used routinely were not identical. The experiments

Fig. 2. Diagrams of mitochondria of amoeba (a) and cyst (b) seen in section to show intra-cristal inclusions

reported here were designed to compare, under standardized conditions, various aspects of *B/r* cultures obtained from different sources.

E. coli B ORNL and *E. coli* B/r ORNL were obtained from the Carnegie Institution, Cold Spring Harbor, about 12 years ago, and have been stocked on refrigerated agar-slants at Oak Ridge National Laboratory since then. They have been transferred at approximately 6-month intervals. These are the cultures most frequently used for work reported from this Laboratory. *E. coli* B CSH and *E. coli* B/r CSH were received from the Carnegie Institution about 3 years ago and have been stocked on refrigerated nutrient-agar. *E. coli* B/r Cornell University, *E. coli* B Institut du Radium, and *E. coli* B/r Institut du Radium were received from the institutions indicated and were refrigerated on arrival. All the cultures were transferred, by mass inoculum, at the beginning of this series of experiments to a medium (total volume, 1 l.) composed of 10 gm. of 'Bacto-Peptone', 1 gm. of dextrose, 1 gm. of yeast extract, 7.6 gm. of dipotassium hydrogen phosphate, 4.5 gm. of potassium dihydrogen phosphate, and 20 gm. of agar. These slants were used as inocula for all experiments.

Preparation of cells and irradiation techniques with X-rays and ultra-violet light are described elsewhere². Determinations of snake-formation and penicillin sensitivity were carried out essentially as described by Witkin³. Optical density was determined with a 'Lumetron' colorimeter with a 650-mμ filter.

Fig. 1 shows that the *B/r* cultures are heterogeneous with regard to X-ray sensitivity. Three of them

* Based on six determinations per value. One S.E. is indicated.

are not strikingly different in sensitivity from the group of three *B* cultures, which form a relatively homogeneous group. To test whether these three *B/r* cultures had 'reverted' to *B*, several criteria were used. Table 1 shows that none of the *B/r* cultures forms 'snakes' after exposure to low doses of ultra-violet light, whereas all the true *B* cultures do. It also shows that the *B/r* cultures are a heterogeneous group with respect to final optical density and that optical density is not correlated with radiation sensitivity. Table 1 also shows the concentration of penicillin required to achieve 100 per cent inhibition of growth as determined by final optical density.

We attempted to determine the sensitivity to ultra-violet radiation of the *B* and *B/r* ORNL and *B* and *B/r* CSH pairs. The results are confounded by a disturbing amount of variation observed in absolute sensitivities from experiment to experiment, even though elaborate precautions were taken to avoid photoreactivation, heat restoration, and other known variables. Nevertheless, it is fair to make certain conclusions based on six independent experiments done for each pair of cultures. Both the ORNL *B/r* and the CSH *B/r* cultures show sigmoid survival curves to ultra-violet radiation. They are each somewhat more resistant than the corresponding *B* cultures, which show more nearly exponential survival. The difference in sensitivity in any one experiment between a *B* and its corresponding *B/r* is never as large as that reported by Witkin².

The results reported here support the contention that cultures labelled *E. coli* *B/r* being used in different laboratories form a genotypically and phenotypically heterogeneous group. *E. coli* *B* cultures are relatively homogeneous.

Cultures of the strain *B/r* differ from each other in their response to X-irradiation, and their physiological capabilities under standardized conditions. Three of the four cultures have an X-ray sensitivity characteristic of *B* cultures, but cannot be classified as 'revertants' since they do not form the 'snakes' characteristic of *B* cultures. Two of these three, although they have strikingly similar X-ray sensitivities, can usually be distinguished from each other on the basis of final optical density and sensitivity to penicillin.

The results obtained with ultra-violet irradiation (2537 Å.), although variable and not done under conditions identical to those used by Witkin², suggest that none of the *B/r* cultures is as strikingly resistant to ultra-violet light as the original *B/r*.

Since the current trend in much radiation bacteriology research is to relate radiation sensitivity to the detailed metabolic mechanisms of cells and to

generalize results from one laboratory to another, our results indicated the need for a note of caution. This is particularly true if one also considers that any one of these cultures may show several forms of sensitivities to X-rays and ultra-violet light, depending on the growth medium and other factors¹. The cultures used in this work were not pre-selected for heterogeneity. They were chosen because they were readily available. It is likely that other groups of *B/r* cultures from other laboratories would be equally heterogeneous. Greater attention to the techniques of maintaining cultures and periodic checking of culture characteristics may allow a more meaningful correlation of the results obtained in different laboratories. We suggest that the designation *E. coli B/r* be reserved only for cultures having all the characteristics originally observed by Witkin.

Chitin Breakdown of Rhizosphere Bacteria

BENECKE¹ was the first to isolate chitinovorous bacteria from Kiel harbour. Since then much work has been done on microbiological breakdown of chitin. Micro-organisms producing chitinase have been observed in fresh and salt waters, in various kinds of soils, in plants and animal bodies, both living and decomposing. It has been reported that pathogenic micro-organisms also break down chitin.

I have studied whether bacteria living in the rhizosphere of superior plants are capable of attacking chitin.

For this purpose chitin has been prepared from the wing-cases of *Melolontha melolontha* L. with the Zechmeister procedure applied also by Gehring². The native chitin obtained in this way was suspended in medium according to Bucherer³. The chitin was present in the medium as the sole source of carbon and nitrogen in amounts of 0.1, 0.25, and 0.5 per cent. Dipotassium hydrogen phosphate and magnesium sulphate (0.03 or 0.1 per cent) were added. The solid medium contained 2 per cent washed agar. In all cases the pH was 7.

Bacteria were isolated on chitin agar and meat agar plates from the rhizospheres of winter wheat (*Triticum vulgare*), sugar-beet (*Beta vulgaris saccharifera*), and false acacia (*Robinia pseudacacia*) with Tepper's⁴ successive washing method (from the dilution of washed and triturated root). About 20 per cent of the bacterial colonies grown on meat agar, tested on both solid and liquid media, proved to be chitinovorous.

The bacterial colonies grown on chitin agar did not show a great variety of types, but the number of individuals was rather high. Their total reached several hundred thousands per 1 gm. of washed root.

From the chitinovorous rhizosphere bacteria of winter wheat and false acacia a rod-shaped, most frequently occurring, active chitinovorous organism—one from each—was selected. These retained their capacity of breaking down chitin for rather a long time.

These bacteria were subjected to detailed examination. In addition to them the capacity of breaking down the chitin of rhizosphere bacteria isolated on non-chitinous media by other workers was also studied: none of the five *Pseudomonas* strains belonging to various serological groups, grown from the rhizosphere of flax by Lovrekovich⁵, tested with the method described above, was found to decompose chitin. Out of the sixteen *Bacterium* strains grown from sugar-beet, Gyurkó⁶ subjected to detailed physiological examination five strains proved to be chitinovorous and the strains kept on meat agar have preserved this property for more than two years.

I wish to thank my colleagues, L. Lovrekovich and P. Gyurkó, for the strains examined.

VIROLOGY

Influenza Virus Sialidase

THE sialidase of influenza virus has been investigated quantitatively using the method recently described by Warren¹ for determining free sialic acid in the presence of the compound bound to mucoprotein substrates. For this work, the substrate used was a mucoid derived from the nest-cementing substance of the swiftlet (*Collocalia* sp.). The crude material, available as Chinese 'edible birds' nest', was extracted with water at 60–65° to yield a product which contained 10 per cent acid-hydrolysable sialic acid and which in high titre inhibited the agglutination of chicken erythrocytes by 'indicator' virus. Active virus was sedimented from freshly gathered chorioallantoic fluid by centrifugation at 35,000g for 90 min. The virus pellet was re-suspended in water to a volume 1/50–1/100 that of the original fluid, effecting thereby a corresponding increment in haemagglutinin titre as well as separation of virus from interfering chromogens present in chorioallantoic fluid.

Aliquots of virus (A2/Japan/305/57) representing a six-fold concentration of infective chorioallantoic fluid were mixed with substrate in phosphate (*M*/15) buffers, pH 4.0–7.8, at 37°, in the proportion 10 µgm. viral nitrogen to 1.4 mgm. substrate. Samples were removed at 10-min. intervals from 0 to 50 min., and were immediately heated to 75° for 10 min., a temperature found to inactivate the virus completely. All samples were either stored frozen or at 4° prior to being analysed simultaneously for sialic acid. Virus alone and solutions of substrate at each pH, after incubation and heating to 75° for 10 min., showed no free sialic acid. The most rapid evolution of chromophore due to enzyme occurred at pH 5.3 and 6.1. These values probably encompassed the pH optimum for this strain, as the enzymatic release of sialic acid at pH 4.0, 7.0 and 7.8 was significantly slower (Fig. 1A). Closely similar results were obtained with three other strains of virus (NWS, FM1 and PR301) and are therefore not given in

Fig. 1. *A*, Liberation of sialic acid (expressed as percentage of total acid-hydrolysable thio-barbituric acid chromophore) in relation to time, at 37°, pH 4.0–7.8. (A2/Japan/305/57 concentrated six-fold from chorioallantoic fluid.) *B*, Relative enzymatic potency, at pH 5.5, 37°, of four strains (A2/Japan/305/57, PR301, FMI, NWS) after concentration and adjustment to the same turbidity.

detail. At each pH the per cent sialic acid released, expressed as a fraction of total acid-hydrolysable chromophore, approached the same maximum (greater than 80 per cent) after incubation at 37° for more than 2 hr. In acetate buffer ($M/100$) at pH 5.5, the sialidase of the A2 strain of virus was inhibited by copper ($M/800$), but not by nickel, zinc, magnesium or manganese, was fully active in the presence of versene (0.02 per cent), and more active at 37° than at 26°. Specific enzymatic activity was proportional to virus concentration. Receptors in *Collocalia* mucin for several indicator strains of influenza virus were inactivated by treatment with concentrated active virus. N-acetylneuraminic acid was identified chromatographically as the only chromogenic substance liberated by viral enzyme from this substrate.

The activity of A2/Japan/305/57 virus was compared with that of FMI, PR301 and NWS viruses. The concentrated viral suspensions were adjusted to the same optical density as measured on a Coleman nephelometer, and assayed at pH 5.5 as described above. Under these conditions, the A2 strain was far more active than either of the other three (Fig. 1*B*), releasing more than 50 per cent of the chromogen in 10 min. As also shown in Fig. 1*B*, the same preparation of concentrated PR301 virus was adsorbed to and eluted from chicken erythrocytes with no loss of enzymatic activity.

The A2 strain of virus was grown in monkey kidney monolayers in 2-oz. prescription bottles. Prior to inoculation, the growth medium was removed, the cells washed and 5 ml. serum-free maintenance solution added (2 parts mixture 199 and 1 part Earle's balanced salt solution). Haemagglutinin appeared in 3–5 days, followed by gross cytopathic changes. 10 ml. of culture fluid from two bottles of the fourth passage were centrifuged at 40,000*g* for 90 min., the pellets resuspended in 0.1–0.2 ml. water, and assayed for enzyme. More than 80 per cent of the bound sialic acid in samples of *Collocalia* mucin was liberated by this virus preparation after incubation at 37° for 16 hr. Normal culture fluid had no enzymatic activity.

The sialidase activity of an A2 strain of influenza (Japan/305/57) appeared to be far greater than that of the other strains tested. Even the few seconds necessary to mix virus with substrate was sufficient

to permit the liberation of 15 per cent of the thio-barbituric acid chromophore. These results are in general agreement with the findings of Seto *et al.*², who concluded that A2 strains showed greater sialidase activity than any other strains previously studied. These authors state that their NWS strain of influenza A had no sialidase activity, whereas the NWS strain used in the present work showed pronounced enzymatic activity, albeit less than that of the A1 strains. The reasons for this discrepancy are not apparent and deserve further investigation.

Reliance on turbidity measurements alone as a quantitative measure of virus particle concentration, and therefore as a basis of comparison, is subject to obvious error because of the possible inclusion of varying amounts of chicken tissue particles in each concentrated virus sediment. It is unlikely, however, that either the extent or variation of tissue contamination from one virus preparation to another was great enough to account for the major differences in enzymatic activity between the A2 strain on one hand and the A and A1 strains on the other. Further comparative investigations are planned with enzyme purified from both egg-grown virus and that produced in monkey kidney cell cultures which appears to be enzymatically just as active.

This work was carried out under the auspices of the Commission on Influenza, Armed Forces Epidemiological Board, and was supported in part by the Office of the Surgeon General, Department of the Army, Washington, D.C., and by grant No. E-3168 from the United States Public Health Service.

A Plaque Technique for the Primary Isolation of Arthropod-borne Viruses

THE demonstration that a wide range of different arthropod-borne viruses could produce plaques in monolayer cultures of chick embryo cells¹ raised the possibility that this technique could be used for the primary isolation of viruses in this group. This point was investigated first by the examination in London of material submitted from Uganda, and later during a visit of one of us to the Virus Research Institute, Entebbe.

During an epidemic of O'nyong-nyong fever in Uganda a number of strains of a virus which was classified as a member of the group A arthropod-borne viruses² was isolated from sera collected from persons during the acute stage of the illness³. One such serum, which had yielded virus by the intracerebral inoculation of one-day-old mice, was forwarded to London packed in ice at 0°C. When dilutions of this serum were tested by the plaque technique, approximately 50 plaques were produced in plates inoculated with 0.5 ml. of a 1:10 dilution, and 3 and 4 plaques developed in plates infected with serum diluted 1:100. The same results were

obtained in a second experiment carried out in London with the same serum sample. Since O'nyong-nyong virus requires a number of serial passages in one-day-old mice before it kills these regularly, the advantages of a direct tissue culture system are obvious.

When this experiment was repeated at Entebbe with another sample from the same batch of serum, once again plaques were produced. However, six other sera collected in the course of the same epidemic which had previously been shown to contain virus failed to produce plaques, although simultaneous tests carried out in one-day-old mice showed that virus was still detectable in four of them by this method. Since these sera had been stored for several months at approximately -60°C . it was felt that fresh material might provide a more useful basis for the comparison of the two techniques. Unfortunately, no fresh material was available from O'nyong-nyong fever patients, but a small outbreak of Rift Valley fever in the vicinity of Entebbe⁴ was investigated by both methods.

One acute phase human serum produced more than 100 plaques per 0.5 ml. of a 1:10 serum dilution, and 22 plaques per 0.5 ml. of a 1:100 dilution. Rift Valley fever virus was isolated from this serum sample by the inoculation of one-day-old mice, the virus titre being $10^{5.5}$ per 0.1 ml. A second human serum also yielded virus by both methods. A mosquito pool suspension from which Rift Valley fever virus had been isolated in mice was retested by both methods after 8 days storage at -20°C . On this occasion no virus was isolated in mice, but one plaque developed in a plate infected with 0.5 ml. of a 1:10 dilution of the mosquito suspension. When material from this plaque was inoculated into mice, Rift Valley fever virus was again recovered. The identity of the virus was established by the inhibition of plaques produced by infected mouse brain suspension around a bead containing a known Rift Valley fever immune serum.

These preliminary experiments indicate that virus isolations may be accomplished by the direct use of the plaque technique, but that the method is probably less sensitive than the use of one-day-old mice, though a much larger series would be required to give a better assessment of the comparative sensitivities of the two methods. The single occasion when virus was recovered in tissue culture and not in mice may be explained in terms of the considerably greater volume of material used in the former system; had an equivalent volume of mosquito suspension been inoculated into further mice, it is probable that virus would have been recovered by that process also.

Although this has not yet been accomplished in practice, a combination of primary isolation in tissue culture, together with plaque inhibition around beads dipped in specific antisera, offers the possibility of virus isolation and identification in a single process.

SOIL SCIENCE

Negative and Positive Adsorption of Chloride by Kaolinite

Schofield and Samson¹ have indicated that the edge face of kaolinite crystals should, under acid conditions, adsorb one chloride ion for each $33\text{ \AA}^2$. They obtained results which showed that on the acid side of neutrality the positive edge charge of a potassium kaolinite was such that it exceeded the negative adsorption of chloride ions resulting from the repulsion of these ions from the negative cleavage face. Further, these authors noted that for conditions more alkaline than about pH 6.5 in 0.005 M sodium chloride the clay exhibited a negative adsorption. When Schofield's² theory was applied to these results, a surface area of $25\text{ m}^2/\text{gm.}$ was obtained and this was lower than the $39\text{ m}^2/\text{gm.}$ obtained by low-temperature nitrogen adsorption. The constant negative adsorption for alkaline conditions was interpreted as being due to the disappearance of positive edge charges. Work reported here, however, shows a positive adsorption dependent on concentration under conditions as alkaline as pH 10. When allowance is made for this positive adsorption the correct value is obtained for the surface area.

The results reported here were obtained for a kaolinite obtained from the pallid zone of a laterite at Rocky Gully in Western Australia. It is the same material designated as kaolin S by Samson and Schofield. The clay (less than 2μ) was washed with M potassium chloride containing 10^{-3} hydrochloric acid; then with water until the chloride ion concentration was less than 10^{-3} M . The required amount of base and electrolyte was added. The clay suspension was centrifuged at low speeds and chloride was determined by an electrometric method in the centrifuged clay and the supernatant liquid.

In Fig. 1 the negative adsorption of a potassium kaolinite at pH 9 can be seen to be considerably less than that expected on the basis of Schofield's theory. It is interesting to note that the value obtained at 0.01 M potassium chloride is in agreement with that obtained by Schofield and Samson. Although the pH of the suspension was 9, it was suspected that the low

Fig. 1. The negative and positive adsorption of chloride by potassium and calcium kaolinite at pH 9. n , Concentration in m.equiv. per ml.

Fig. 2. Effect of pH on the positive adsorption of chloride by calcium kaolinite

values for the negative adsorption were caused by a concomitant positive adsorption. The kaolinite was treated with sodium polymetaphosphate (6 m.equiv./100 gm. adsorbed) and the results obtained by the negative adsorption of chloride then agreed with the theoretical expectation. Since this was considered only circumstantial evidence for the existence of chloride uptake at pH 9, more direct proof was sought. Since the negative adsorption of chloride for a clay saturated with a divalent cation is considerably less than for a monovalent ion, the kaolinite was saturated with calcium and it was found that positive adsorption predominated and also that the chloride adsorption was dependent on concentration. When the potassium kaolinite results were corrected for the amount of positive adsorption for the calcium kaolinite, the arrows in Fig. 1 indicate that the cleavage face is in fact repelling chloride ions in the expected fashion. It is pointed out that since there would be some negative adsorption of the calcium kaolinite this procedure would under-estimate the positive charge and hence the corrections applied to the potassium kaolinite would be slight under-estimates.

In Fig. 2 the effect of pH and electrolyte concentration on the adsorption of chloride by a calcium kaolinite is shown. At about pH 7 in 0.1 M calcium chloride there is a transition from concentration-dependent to concentration-independent chloride adsorption.

The ceiling value of 3 m.equiv./100 gm. attained at about pH 3 represents an edge surface area of 6 m.²/gm. and this is 14 per cent of the B.E.T. area for the material. Cashen has reported edge areas of 11 and 19 per cent for Mercks and Peerless kaolin. These were measured by titration of the kaolins with cetyl trimethyl ammonium bromide before and after treatment with pyrophosphate or oxalic acid, both of which would render the edge face negative.

As noted by Schofield and Samson this kaolinite contains a small quantity of iron oxide (< 2 per cent goethite) as impurity but this would only affect the results to a minor extent.

These investigations are continuing and work on the importance of edge faces as the site of phosphate fixation are in progress.

MATHEMATICS

William Stroud and Quantity Calculus

THE convention of representing physical quantities, rather than their measures, by letters is said to have been "devised in the eighties of last century by that versatile genius Prof. William Stroud, of Leeds University"¹. A succession of teachers of applied mechanics at the Royal Naval College, Greenwich (J. B. Henderson, B. P. Haigh, J. G. Docherty, F. W. Thorne and A. C. Walshaw), and other teachers have always referred to this convention as the 'Stroud system'². It is the main purpose of this communication to present some reasons why this attribution is unsatisfactory and why it would be better to replace it by the term 'quantity calculus' used by E. A. Guggenheim and others³.

There is no written evidence that William Stroud ever used the conventions of quantity calculus. The following question from one of his examination papers shows that he did not use it in his teaching: "The thermo-electric power of Cu—Pb = 0.0124 (67 + t) and for Fe—Pb = 0.042 (357 - t). Find the E.M.F. in a Cu—Fe circuit whose junctions are at 100° C. and 200° C."⁴.

There is evidence that others were advocating and using quantity calculus before or at the time that William Stroud is said to have been teaching it. Following the publication of J. B. Henderson's account of the 'Stroud system'¹, E. H. Neville⁵ immediately pointed out that J. D. Everett⁶ had certainly used quantity calculus in 1879, though, I would add, not always in a consistent manner. It is of interest to note that William Stroud was certainly acquainted with J. D. Everett's text-books, because one of the recommended books for the first-year course in physics at the Yorkshire College was Deschanel's "Natural Philosophy", Vol. 1, thirteenth edition, which was translated and edited by J. D. Everett⁷. The first clear expression of the principles of quantity calculus is undoubtedly A. Lodge's very concise presentation of its conventions under the significant title: "The Multiplication and Division of Concrete Quantities"⁸.

In view of these historical difficulties, it would appear to be best to speak of 'quantity calculus' rather than of the 'Stroud system'.

I wish to acknowledge the help I have received from Miss D. M. Leak, of the Brotherton Library, University of Leeds; the Directors of Barr and Stroud, Ltd., Glasgow; and Prof. F. W. Thorne, Dr. A. C. Walshaw and Dr. J. G. Docherty.

FORTHCOMING EVENTS

(Meetings marked with an asterisk * are open to the public)

Monday, October 17

UNIVERSITY OF LONDON (at Senate House, London, W.C.1), at 5.15 p.m.—Prof. J. Piaget (International Bureau of Education, Geneva): "The Thinking of Young Children".*

UNIVERSITY OF LONDON (at Queen Elizabeth College, 61-67 Campden Hill Road, London, W.8), at 5.30 p.m.—Prof. A. J. Ayer: "Contemporary British Philosophy".*

INSTITUTE OF METALS, LONDON LOCAL SECTION (joint meeting with the INSTITUTE OF METAL FINISHING, at the Northampton Polytechnic, St. John Street, London, E.C.1), at 6.15 p.m.—Mr. C. Williams: "Electroplating Processes and Effect on Fatigue Strength and Embrittlement of the Substrate".

INSTITUTE OF NAVIGATION (at the Royal Geographical Society 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Dr. Eric Axelrod: "Henry the Navigator and the Sea Route to India" (First Eva G. R. Taylor Lecture).

Tuesday, October 18

UNIVERSITY COLLEGE (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. H. Kalmus: "The Biology of Fighting".*

UNIVERSITY OF LONDON (in the Great Hall, Queen Mary College, Mile End Road, London, E.1), at 1.30 p.m.—Sir Vivian Fuchs: "Antarctica Today".*

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. F. Hirzebruch (University of Bonn): "The Role of Characteristic Classes in Algebraic Topology".* (Further lectures on October 19 and 20.)

BRITISH ORNITHOLOGISTS' UNION (joint meeting with the BRITISH ORNITHOLOGISTS' CLUB, in the new Lecture Hall of the British Museum (Natural History), Cromwell Road, London, S.W.7), at 6 p.m.—Annual Scientific Meeting. Dr. A. J. Cain: "Tropical Forest and Bird Ecology" (illustrated with slides and a film).

OIL AND COLOUR CHEMISTS' ASSOCIATION, LONDON SECTION (at Manson House, 28 Portland Place, London, W.1), at 7 p.m.—Mr. R. D. Griminski and Mr. F. M. P. Meredith: "The Lacquering of Aluminium-Magnesium Alloys".

Wednesday, October 19

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Duane Road, London, W.12), at 2 p.m.—Dr. K. Lowe: "Tests of Renal Function".*

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. J. B. Prentice: "The Stratigraphy of the Upper Carboniferous Rocks of the Bideford Region, North Devon"; Dr. D. C. Knill and Dr. J. L. Knill: "Time Relations Between Folding, Metamorphism and the Emplacement of Granite in Roanquil, Co. Donegal".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Scientific Papers.

INSTITUTE OF FUEL (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Discussion on "Pulverized Fuel Flames", led by Mr. G. G. Thurlow.*

INSTITUTION OF ELECTRICAL ENGINEERS, SUPPLY SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. E. L. Robinson: "The Developing Engineer" (Chairman's Address).

ROYAL MICROSCOPICAL SOCIETY (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p.m.—Prof. R. Ruggles Gates F.R.S.: "The Histology of Skin Pigmentation".

CEMENT AND CONCRETE ASSOCIATION (at the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Mr. F. R. Beldon: "Lift Slab Design and Construction".

SOCIETY OF CHEMICAL INDUSTRY, CORROSION GROUP (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. C. Edeleanu and Mr. J. B. Cotton: "Anodic Protection". (A) "Principles". (B) "Practical Application".

BRITISH INSTITUTION OF RADIO ENGINEERS, MEDICAL AND BIOLOGICAL ELECTRONICS AND COMPUTER GROUPS (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Symposium on "The Use of Computers in Biological Waveform Analysis".

Thursday, October 20

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. J. H. Cullomon: "The Danish East Greenland Expeditions, 1957-58".*

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—October General Meeting.

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Dr. V. P. Whitaker: "The Subcellular Localisation of Neurohormonal Agents".* (Further lecture on October 27)

UNIVERSITY OF LONDON INSTITUTE OF EDUCATION (in the Great Hall, Goldsmiths' College, New Cross, London, S.E.14), at 6 p.m.—Mr. A. B. Clegg: "An Extra Year".* (Fifth of a series of lectures on "The Future of Education".)

UNIVERSITY OF LONDON (at Senate House, London, W.C.1), at 5.30 p.m.—Prof. C. H. Waddington, F.R.S.: "The Significance of Developmental Biology".* (First of fifteen lectures on "The Scientific Basis of Medicine", organized by the British Postgraduate Medical Federation.)

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS GROUP (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. L. E. Akers: "The Manufacture and Properties of Wood Chipboards".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the SOUTH-EAST ESSEX TECHNICAL COLLEGE SCIENTIFIC SOCIETY, at the South-East Essex Technical College, Longbridge Road, Dagenham, Essex), at 7 p.m.—Dr. G. I. P. Levenson: "Some Chemical Aspects of Colour Photography".

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 28 Portland Place, London, W.1), at 7.30 p.m.—Opening Meeting of the 54th Session. Dr. Telford Work will show a film entitled "Kyasaur Forest Disease in India".

BRITISH INSTITUTE OF RADIOLOGY (in the Beld-Knox Hall, 32 Welbeck Street, London, W.1), at 8 p.m.—Mr. J. W. D. Bull: "The History of Neuroradiology" (Presidential Address).

UNIVERSITY OF LONDON (at Wye College, Wye, Ashford, Kent), at 8 p.m.—Sir Eric Ashby: "Reflections on Soviet Education".*

Friday, October 21

PHOTOELECTRIC SPECTROMETRY GROUP (in the Department of Chemistry, Imperial College of Science and Technology, London, S.W.7), at 2 p.m.—Meeting on "Recording Ultraviolet Spectrophotometers".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. S. H. Clarke: "Fire Research".

Saturday, October 22

BIOCHEMICAL SOCIETY (at the National Institute for Medical Research, The Ridgeway, Mill Hill, London, N.W.7), at 10.25 a.m.—Scientific Papers.

WORKERS' EDUCATIONAL ASSOCIATION (at Mullard House, Torrington Place, London, W.C.1), at 2 p.m.—Meeting on "Science and the Arts".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the date mentioned:

HEAD (graduate, with good industrial and teaching experience) OF THE ENGINEERING DEPARTMENT (Civil, Electrical and Mechanical Engineering)—The Acting-Principal, Dudley and Staffordshire Technical College, Dudley (October 21).

SENIOR LECTURER/LECTURER (preferably in possession of a medical qualification and also a higher degree) IN PHYSIOLOGY—The Secretary, London Hospital Medical College (University of London), Turner Street, London, E.1 (October 21).

SENIOR LECTURER (with high qualifications and wide experience) IN PHYSICS to teach to honours degree level; and an ASSISTANT, Grade B, IN PHYSICS—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (October 21).

LECTURER IN STATISTICS—The Registrar, University College of North Staffordshire, Keele, Staffs. (October 24).

RESEARCH FELLOW IN ORGANIC CHEMISTRY to work on the study of factors affecting polymerization of compounds containing boron-nitrogen bonds—The Registrar, The University, Nottingham (October 29).

SCIENTIFIC OFFICER (with a first- or second-class honours degree with physical or inorganic chemistry as the principal subject) IN THE DEPARTMENT OF PEDOLOGY, for work which will involve investigations upon soil formation processes with a physico-chemical bias—The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (October 29).

ASSISTANT LECTURER or DEMONSTRATOR IN PATHOLOGY—The Registrar, The University, Manchester (October 31).

CHAIR OF MATHEMATICS—The Registrar, The University, Hull (October 31).

LECTURER IN THE UNIVERSITY COMPUTING LABORATORY, Newcastle upon Tyne—The Registrar, University of Durham, 46 North Bailey, Durham (October 31).

LECTURER or ASSISTANT LECTURER (qualified in pure or applied mathematics) IN MATHEMATICS—The Registrar, University College of North Staffordshire, Keele, Staffs. (October 31).

FELLOW (with field and laboratory experience in virology and the epidemiology of insect-transmitted viral diseases) IN THE DEPARTMENT OF MICROBIOLOGY, John Curtin School of Medical Research, Australian National University, to work on the epidemiology of arthropod-borne virus infections in Australia and the islands to the north of Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, November 4).

LECTURER (with qualifications in pure mathematics) IN MATHEMATICS—The Secretary, The University, 38 North Bailey, Durham (November 12).

RESEARCH DEMONSTRATOR (preferably with experience and interest in field and soil mycology) IN MYCOLOGY IN THE DEPARTMENT OF BOTANY—The Registrar, University College of North Wales, Bangor, North Wales (November 14).

SENIOR ASSISTANT LIBRARIAN (preferably aged 25 to 35 with a good knowledge of chemical literature and experience in an industrial or other special library)—The General Secretary, The Chemical Society, Burlington House, Piccadilly, London, W.1 (November 14).

CHAIR OF CHEMISTRY, and a READER IN PHYSICAL CHEMISTRY AT THE UNIVERSITY OF KHARTOUM—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 15).

LECTURER (with an honours degree in zoology) IN ZOOLOGY AT THE UNIVERSITY OF CANTERBURY, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, November 15).

READER or SENIOR LECTURER or LECTURER IN AGRICULTURAL BIOCHEMISTRY; and a READER or SENIOR LECTURER or LECTURER IN ENTOMOLOGY IN THE FACULTY OF AGRICULTURE, University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 15).

ASSISTANT LECTURERS (2) IN THE DEPARTMENT OF BIOCHEMISTRY—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (November 19).

CHAIR OF GEOGRAPHY AT THE LONDON SCHOOL OF ECONOMICS—The Academic Registrar, University of London, Senate House, London, W.C.1 (November 21).

CHAIR OF PSYCHOLOGY—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (November 26).

LECTURER/SENIOR LECTURER and a LECTURER (with research and teaching experience in some branch of pharmaceutical chemistry) IN PHARMACY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, November 26).

CHAIR OF PHILOSOPHY—The Registrar, The University, Hull (November 30).

LECTURER IN PSYCHOLOGY at the University of Tasmania, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, November 30).

LECTURER (preferably with special qualifications in physiology or genetics) IN BOTANY at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, November 30).

ASSISTANT LECTURER, Grade "R" (with a good honours degree or equivalent with some teaching and/or industrial experience, and an interest in research) IN CHEMISTRY, to specialize in inorganic or physical chemistry to Grad.R.I.C. and B.Sc. General standard—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham.

BIOLOGIST (with a good degree in physiology or zoology and considerable research experience, preferably with spermatozoa) to join a small research team investigating cervical mucus, with particular reference to problems of fertility—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref. 60/18.

GEOLOGISTS (with a degree of a recognized university with either first- or upper second-class honours in geology, two years approved postgraduate experience, and preferably some specialization in mining geology) IN THE GEOLOGICAL SURVEYS DEPARTMENT, Federation of Malaya—The Recruitment and Personnel Division, Malaya House, 57 Trafalgar Square, London, W.C.2.

HEAD (medical graduate or science graduate with a higher degree) OF THE DIVISION OF VIROLOGY, for duties which include the supervision of diagnostic services and the carrying out of special investigations on and research into virus diseases—The Director, Institute of Medical and Veterinary Science, P.O. Box 14, Rundle Street, Adelaide, South Australia.

MICROBIOLOGIST (previous medical experience not essential) IN THE BACTERIOLOGY LABORATORY OF THE DEPARTMENT OF CLINICAL PATHOLOGY—The Administrator and Secretary, University College Hospital, Gower Street, London, W.C.1.

POSTDOCTORATE FELLOWS IN BIOCHEMISTRY, CHEMISTRY, ENGINEERING AND METALLURGY, PARASITOLOGY, PHYSIOGRAPHY, PHYSICS OR TEXTILES—The Personnel Officer, Ontario Research Foundation, 43 Queen's Park Crescent, Toronto, Ontario, Canada.

PROFESSORS (preferably with Ph.D. or M.Sc.) OF PHYSICS, CHEMISTRY, and BIOLOGY at the Medical College, Mosul, Iraq—The Director, Recruitment Department, British Council, 65 Davies Street, London, W.1, quoting N.14.N(60).

RESEARCH ASSISTANT (graduate in biochemistry, chemistry or physiology) for research on metabolic disturbances in neurosurgical patients—Dr. H. M. B. Buckell, Department of Pathology, Atkinson Morley's Hospital, Copse Hill, Wimbledon, London, S.W.20.

RESEARCH FELLOWS IN PHYSICS for research on optical and electronic instrumentation for high energy physics in connexion with the experimental programme of the 7 GeV. Synchrotron at the Rutherford Laboratory, Harwell—Prof. G. W. Hutchings, Department of Physics, The University, Highfield, Southampton.

TECHNICIAN to cut and stain histological sections in connexion with a research programme in the DEPARTMENT OF PHYSIOLOGICAL CHEMISTRY—The Assistant Bursar, The University, Reading.

EDUCATION FOR AN INDUSTRIAL SOCIETY

SO many conferences of a self-duplicating nature are arranged by educationists in industry that the question often arises as to what the organizers do when they are not taking in each other's washing. As recent reports show, the British Association for Commercial and Industrial Education has not been entirely free from the criticism that some of the many conferences it arranges are but repetitions of previous ones and attended by the same round of converted disciples¹. It is gratifying, therefore, to direct attention to the Association's annual conference which was held at Cambridge during September 22-24, 1960². This was the kind of conference which could not fail to stimulate those attending; there was a co-ordinating theme which was readily apparent and the active participants were there because they—nearly all—had something to say, and said it with conviction. In addition, the organizers had prepared advance copies of each paper containing, as introduction, a summary of a recent Government report which the speaker had been invited to consider. As a result conference members were presented with the opportunity to examine the whole broad front of educational advance and the way it could affect young people in our industrial society.

The Albemarle, Crowther, McMeeking, Carr, Anderson, and Willis Jackson Reports were all considered, as were the work of the Industrial Training Council and the Government's new proposals for management studies. With one exception, each speaker was not only able to present a review from intimate knowledge of a report but also was able to illuminate passages which had hitherto been dark.

The Albemarle Report, for example, was considered by M. J. W. Clapham, a director of Imperial Chemical Industries, Ltd., who showed how a sceptic came to support the ten-year development programme for young people put forward by an enthusiastic committee. The approach itself is one which should commend itself to all who are appointed to important national committees and may well explain why the Minister of Education was able to announce his acceptance of the committee's proposals on the same day that the Report was published.

It was unfortunate that a Report which has been far less favourably received—and especially by industry—should not have been presented in a similar manner. Instead, Miss M. G. Green, a member of the Central Advisory Council for Education (England), which produced the Crowther Report, chose simply to summarize its main recommendations for those who cannot or will not read. So much controversy has arisen over the priorities and timings of the Committee's main recommendations that those who

support them should not throw away opportunities to gain public sympathy; many industrialists believe that the Crowther Committee has mixed up its priorities and has produced a Report lacking urgency and conviction.

The Carr Report on apprenticeship training was considered particularly in relation to its foster-child, the Industrial Training Council. While Lord McCordale, chairman of the Industrial Training Council, strove loyally to extol the work of his gently moving organization, the revelations of the Minister of Labour, the Right Hon. John Hare, showed that industry has failed lamentably to accept the Government and Industrial Training Council exhortations to provide greater facilities whereby school-leavers can systematically learn the skills of a craft. From the Minister's address it became apparent that the short-sightedness and remissness of employers could, inside a generation, starve the country of the skilled and adaptable workers who are essential to an economy based on science and technology. The Government has already intervened by providing places for three hundred apprenticeships, and the portents are that, with the failure of industry, massive Government intervention is inevitable.

Reviewing the Report which bore his name, Sir Colin Anderson did not hesitate to speak "between the lines", and made it clear why the majority of his Committee believes that the way to the university should no longer be controlled by the means or wishes of the parents. Further education should be something which the student can secure for himself by the use of his own brains, initiative and energy, even if his parents are uninterested.

The danger confronting the universities, and especially the older foundations, in becoming public trustees for the higher education of the nation—which implies much of its financial as well as other resources—was also examined by Sir Colin, who showed that the universities need lose none of their spiritual autonomy in a free, industrialized society.

The sponsors of the conference may have combined joint consideration of the McMeeking Report with the new scheme for management studies for their own good reasons. Despite the garnishing, the dismal failure of efforts to build up the National Certificates in Commerce since the publication of the McMeeking Report some eighteen months ago has led to considerable speculation about the Government's rejection of a Working Party's recommendations to develop an Intermediate Certificate in Management Studies and its virtual substitution by the new Higher National Certificate in Business Studies. Many members of the conference felt that the Ministry of Education

had placed administrative convenience before the genuine needs of management students and was determined to push the latter into courses in business studies. This, no doubt, will shore up the precarious courses in business studies by providing enough students and teachers to make classes worth running. Mr. J. C. W. Stead, a director of Batchelor Peas, who was a member of the Working Party appointed to examine the Scheme of Management Studies, was right to insist that a fundamental mistake had been made by the Ministry in trying "to combine a course which purports to help people to an understanding of management principles with a course which sets out to attract young people, in some cases straight from school, at an age of 18, for the purpose of studying certain commercial subjects". Before proceeding with this irreconcilable union, the Ministry should seek the advice of the Committee set up under the chairmanship of Sir Keith Joseph to consider the establishment of courses in management studies at one or more universities. The Ministry is revealing the same attitude to management studies as it did to science education some forty to fifty years ago. It should encourage part-time students who come up the hard way to extend their knowledge with studies of management principles and practice; such students bring qualities to industry which are not always present in management trainees recruited from graduates.

Sir Willis Jackson dealt in an exemplary manner with his own Report on the Supply and Training of Teachers for Technical Colleges. He described separately the proposals contained in the Report and action taken afterwards. The pay of full-time technical teachers, for example, was raised by the Burnham Committee in 1959 and has been followed by appreciable increases in the scales of part-time teachers. Consultancy work is beginning to develop in the advanced colleges, and more teachers are following courses of study leading to higher qualifications. The supply of part-time lecturers of standing to such day students is slowly increasing but the disparity in salaries is proving a considerable barrier to the transfer of senior scientific Civil Servants. The short courses for training serving teachers to teach better have been extended, and a new teachers' training college is being developed at Wolverhampton. Enough money has been raised to establish the Staff College for technical teachers and the location of the College and appointment of the director of studies should shortly be made. Sir Willis also described the arrangements for increasing the total number of teachers for technical institutions and deserves considerable praise for the part he is playing in this.

The conference was one which the British Association for Commercial and Industrial Education can feel proud to have organized. Those attending should now see that the weighty matters discussed are not allowed to be forgotten in their local activities.

LIFE IN THE SOIL

Living Earth

By Peter Farb. Pp. ix+178+8 plates. (London: Constable and Co., Ltd., 1960.) 21s. net.

ON learning, from the inside flap of the dust-jacket, that the author of this book "was formerly a Feature Editor of *Argosy* magazine", and further, from the author's own preface, that his "approach has been that of the science reporter", the intending reader might feel (as I did) some slight apprehension lest he should be in for a piece of journalistic pot-boiling. But he would be quite wrong. This is a soberly, sanely and attractively written work, presenting a comprehensive and often entertaining picture of what is at present known of the teeming inhabitants of the soil, and of their varied conditions of life. Even for many readers with a broad knowledge of natural history it will certainly provide an introduction to an entirely new world; and for once—*mirabile dictu*—a reviewer may be permitted to agree with a publisher's blurb, when it uses such enthusiastic expressions of approval as the "fascination" and "excitement" of the book.

Mr. Farb is an American, living in the State of New York (he was formerly secretary of the New York Entomological Society), and his book has naturally a New World emphasis. He discusses the life of the soil under the three main headings of "Forests", "Grasslands", and "Deserts", with an introductory section on "The Living Soil", and a concluding section on "Mutual Survival". A four-and-a-half page descriptive bibliography and a (not entirely adequate) index complete the work.

One is tempted to quote liberally from a book that is so full of good things. A feature that especially commends itself is the author's emphasis on the interdependence of all forms of life, their intimate mutual relationships, and their complex interactions with their environment, forming with it one indivisible whole. Of certain 'wayfarers from the soil' he writes: "We can but divine their rôles in the intricate web of grassland life; for no creature of the soil stands alone—all are interwoven, their pasts and their futures, in the economy of a piece of earth" (p. 130). "The dividing line between animals and plants is often a slim and artificial one . . . The line between living and non-living forms is not so sharp as [was] once supposed" (p. 15).

The author has the valuable gift, in the midst of his factual reporting, of lifting his eyes to wider horizons and pointing out some of the implications of the facts he records. In the course of his remarks on the soil-dwelling social insects, to which he devotes much space, he says of the termites: "Termites are a very ancient form of insect life . . . going back well over 250 million years . . . In their great age, termites question one of the popular beliefs about evolution—that all living things on the planet are progressing toward more perfect organisms. Termites reached their full structural and social development, including their very complicated system of castes, in the Tertiary period, many million years ago. Since then, they have neither advanced nor fallen by the wayside, but now populate the earth in their age-old pattern" (p. 83). "Many experimenters have looked upon the termite nest as actually a superorganism in which each of the castes functions as a part of a single, larger organism . . . The superorganism theory . . . has many biological obstacles

to meet . . . yet in the hot termite mounds may lie an answer to one of the most perplexing questions about life itself" (p. 91). How faithfully certain aspects of human activity are sometimes mirrored in the lives of creatures allegedly 'lower' in the scale! One of Mr. Farb's most dramatic and vivid passages is that in which he describes the seasonal sequence of events in a wasps' nest (pp. 91-94). Towards the end of the summer, after the departure of the new queens and kings, "a madness begins to eat away at the very foundations of the city . . . workers take to devouring the larvæ; but still unsated, they abuse, then torture, the young. An orgy has begun that will end only with the death of the city . . . They rush through the combs looting and destroying. The queen is assassinated, and every worker becomes a queen. It is democracy in its most horrible form."

The interesting and important part played by root secretions, or 'diffusates' (this word, incidentally, is missing from the index), is touched upon in many places. While their primary function is no doubt to provide some kind of benefit to the owner of the root—for example, the encouragement of the growth of symbiotic or otherwise beneficial fungi and bacteria in its immediate vicinity, or the prevention of the growth of certain other plant competitors within a certain radius—it is evident that many other organisms have 'cashed in' on this secretory activity of root-systems for their own ends. It is found, for example, that root diffusates exercise a positive attraction to wireworms, the larvæ of click-beetles (Elateridae), which use the roots as food; that they act as a stimulant to the awakening of encysted nematodes, which then enter the root and commence their work of destruction; and that they also provide the stimulus for the germination of the seeds of certain pernicious root-parasites, such as *Striga* (Scrophulariaceae). It is clear that these chemical substances are one of the most vital factors in the complex interactions of organisms in the soil.

A few points call for criticism. The photographs are, on the whole, very good, but the text-figures are often poor. No list, either of plates or of text-figures, is supplied. Misprints are commendably few—curiously enough consisting almost entirely either of singulars for plural, or the reverse: the fractions on p. 67 ("1/100ths", etc.) are very odd. Some startlingly untrue statements are clearly slips: "the most obvious part of the fungus . . . is its vegetative organ, the toadstool" (p. 66); "this animal [the Mycetozoa swarm-spore] divides a few times by simple fusion" (p. 71). Some may have been due to misunderstanding of informants: "most orchids have little or no chlorophyll" (p. 63). Certain remarks betray carelessness of phraseology or looseness of thought: "Alfred R. Wallace . . . co-discoverer with Darwin of the theory of evolution" (p. 75) (How does one 'discover' a 'theory'!); "Linnaeus, the Swedish botanist who invented the modern method of classifying living things into various categories" (p. 83). But there are one or two remarks over which I am still scratching my head. "This mold [the Mycetozoa] may well be 'the slime of the earth' of the Book of Genesis" (p. 70). Has Mr. Farb had access to a new and shattering Hebrew manuscript? Or has he merely got a bit mixed between Genesis ii, 7 and xi, 3? "On a beastly summer day in South Africa . . ." (p. 84). Never having been in South Africa, I have no idea whether its summer can be really as unpleasant as the author seems to imply; but his scathing epithet

seems to rise from the page with the impact of a blow to the solar plexus, leaving one slightly winded. Finally: "Dr. Livingstone, before being hounded by the intrepid Stanley, was an enthusiastic naturalist" (p. 84). Poor, meek, weak-minded Livingstone! Poor, splendid, overbearing Stanley! Do they really deserve these aspersions?

But it is not necessary to end on a frivolous note. Mr. Farb has written a most interesting, thought-provoking and worthwhile book.

H. K. AIRY SHAW

THE STRUCTURE OF BACTERIA

The Bacteria

A Treatise on Structure and Function. Edited by I. C. Gunsalus and Roger Y. Stanier. Vol. 1: Structure. Pp. xiv+513. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1960.) 13 dollars.

"HERETOFORE, there has been no comprehensive source of information about modern knowledge of the general biological properties of bacteria." This statement of the editors is the clue to this volume and, presumably, to the four others projected which will cover the fields of metabolism, biosynthesis, growth and heredity, and will be welcomed by the growing legion of bacteriologists whose interests lie primarily in the bacteria themselves and not in the immediate medical or industrial applications of bacterial properties.

There are ten chapters, each contributed by an internationally distinguished worker, which bear the following headings: "The Bacterial Protoplasm—Composition and Organization"; "The Internal Structure of the Cell"; "Surface Layers of the Bacterial Cell"; "Movement"; "Morphology of Bacterial Spores, Their Development and Germination"; "Bacterial Protoplasts"; "L-Forms of Bacteria"; "Bacterial Viruses—Structure and Function"; "Antigenic Analysis of Cell Structure"; and "Localization of Enzymes in Bacteria". Chapter 1 is a general introductory survey.

As might be expected in a treatise by many authors total co-ordination was difficult, but it is perhaps a feature of strength rather than weakness that some overlapping occurs. Occasionally, seeming contradictions have crept in, as: "Even the processes involved in all forms of motion of living organisms seem to share a common basic metabolism; stimulation of contractile protein with ATPase activity by the common substrate adenosine triphosphate" (p. 4), while the same author on p. 26 states, "No report of ATPase activity in flagellar protein has been made". The enigma is partially solved in the section on movement (p. 173), "Not very much is known about the energy supply of active flagella. . . . De Robertis and Franchi claim that bacterial flagella contract in the presence of ATP. De Robertis and Peluffo have found that ATP enhances the motility of *Proteus vulgaris*. On the other hand, Barlow and Blum found no ATPase activity in flagella preparations". Such conflict is the seed of science, and as the text is generously impregnated with references (more than 1,500) the reader can easily discover the sources of the claims made and judge them for himself.

The authors have refrained from dogmatism, and long-standing disputes such as the nature of bacterial

nuclear material, the method of its division and whether flagellar movement is the cause or the result of the movement of the organism, are treated impartially. The chapter on bacterial viruses appears short when viewed against the activity and interest in this field—less than twenty pages excluding illustrations. Many of the illustrations included in the volume are outstanding examples of the advances made in technique, especially with the electron microscope.

The various topics are clearly sub-headed and used in conjunction with the detailed contents, and author and subject indexes make this a very accessible reference work and augurs well that the completed treatise will be the most significant addition to bacteriological literature for some years. It will also be expensive.

L. B. QUESNEL

GENES AND PROTEINS

The Molecular Basis of Evolution

By Christian B. Anfinsen. Pp. xiii+228. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 56s. net.

AT first glance, some features of this book are likely to seem a bit disconcerting. At the present time there are three fields of inquiry which have considerable claims to be considered, both particularly active and peculiarly important for general biology: one is the evolutionary process; the other two, which are closely connected, are the sub-structure of genes, and the configuration of the protein molecule. Dr. Anfinsen seems to be claiming to have gathered all three together into the confines of a comparatively small book. Its dust-cover states that he "regards the evolutionary process as the integrated form of genetics and protein chemistry". Unless the word 'genetics', which is a notoriously elastic one, is here taken to include such matters as natural selection, mutation, species divergence and so on, this way of regarding evolution would certainly seem to be a bad case of Hamlet without the Prince of Denmark.

However, it would be a pity to take these first impressions too seriously. Apart from reproducing a few well-known figures from a book by G. G. Simpson in the first chapter, and giving a short outline of elementary genetics in the second, the author in fact pays little attention to the subject of evolution. What he has actually produced is a summary of recent work on the relation between the sub-structure of the genes and the proteins which they specify. Most of this account follows the lines which are already becoming recognized as orthodox. For example, in the description of studies of the mechanism of chromosome duplication with the aid of radioactive labels, Anfinsen describes the work of Taylor and his associates, in which the chromosomes did what they had been expected to do, but does not mention that of Plaut and Mazia, who came to different conclusions, although he does add a footnote concerning the results of La Cour and Pelc, which also differed from those of Taylor.

The writing in this part of the book is rather slapdash and not very accurate. For example, in discussing Taylor's work on chromosome duplication on page 59 the author writes: "In an occasional 'second generation' pair of chromosomes, individual sister chromatids were labelled for only part of their length . . . and in such cases the corresponding

portion of the other chromatid showed radioactivity. This behaviour is to be expected for crossing-over and resembles the cytological observations that have been made for the chromosomes of other species (e.g. the giant salivary gland chromosomes of *Drosophila*)". Actually the situation is that when crossing-over occurred in Taylor's chromosomes, and a chromatid was found to be labelled for only part of its length, the corresponding part of the sister chromatid did *not* show radioactivity. Moreover, no phenomena comparable to crossing-over occur in the giant salivary gland chromosomes of *Drosophila*. Again, to give another example, on p. 88 Anfinsen writes: "As we discussed in connection with the 'lozenge' genes of *Drosophila* (Chapter 2), three closely linked genetic loci all appear to be part of the same functional unit since crosses between double heterozygotes bearing both mutant loci on the *same* strand of the chromosome duplex (i.e. in the *cis* arrangement) produced wild-type recombinants, whereas crosses between double heterozygotes in the *trans* arrangement did not". This sentence suggests a state of complete confusion. In the first place the phrase 'chromosome duplex' is normally used to refer to the two helically twisted strands which together make up the deoxyribonucleic acid molecule; and the point at issue is not whether the mutant loci are on the same or different strands in such a duplex, but whether they are on the same or different chromosomes. Then the well-known '*cis-trans*' criterion', to which Anfinsen is referring, does not turn on the nature of the recombinants which may be produced by crossing the double heterozygotes, but on the simple fact whether the double heterozygote itself shows the mutant character or not. Anfinsen actually describes this quite correctly in Chapter 2. Presumably the confusion that has arisen in the passage quoted was due simply to some lapse of attention.

It is when we pass from the more genetical parts of the book to the more chemical sections that its true value begins to emerge. Anfinsen is himself a protein chemist, and his handling of the chemical aspects of his subject is much more confident than that of the genetical material and, at least to a genetical reader, carries much more conviction. He provides an admirably clear account of recent work on the analysis of the sequence of amino-acids in various proteins, and of attempts to unravel their secondary and tertiary structures. This is illustrated with a large number of very clear diagrams. It will undoubtedly be extremely useful and suggestive to many biologists who are interested in this topic without being expert in it. Thus, in spite of certain inadequacies, therefore, his book has very real value.

C. H. WADDINGTON

GENETIC ANTHROPOLOGY

The Mothers

By Robert Briffault. Abridged, with an Introduction by Gordon Rattray Taylor. Pp. 451. (London: George Allen and Unwin, Ltd., 1959.) 36s. net.

THE re-publication of "The Mothers", reduced from more than two thousand pages to less than five hundred, is intended to make it available to "the maximum possible public". It is doubtful, however, whether any great interest in it will be aroused among social scientists, except as an example of a

phase in the development of anthropology. There is a fundamental difference between an attempt such as Briffault's to reconstruct the hypothetical course of the development of the institution of the family over the ages, and modern anthropology, *pace* Prof. Gordon Childe and Dr. Freud. Indeed, genetic anthropology is, in Prof. Evans-Pritchard's phrase, now generally regarded as an "attempt to explain what we know something about by what we know next to nothing about"; the reaction against it occurred at the beginning of the present century, and developments since then have been along quite different lines.

On the other hand, the controversy between Briffault and Westermarck, which was waged with such bitterness a generation ago, still has a direct interest for us to-day. The immediate issue at stake is no longer a live one; it centred round the problem whether the origin of the family is to be found in a primitive matriarchy (as Briffault thought), or in the activity of masculine jealousy and possessiveness and therefore, as Westermarck held, a patriarchy. The significance of the conflict for the contemporary social scientist is in the manner in which the conclusions of each of the protagonists was built into his work by his primary assumptions; this also determined the selection of the evidence which was discussed as well as the interpretation placed on it.

"The Mothers" may thus be regarded as a brilliant piece of special pleading, and may well live in the literature of the social sciences as the classic example of illustrative or interpretative, rather than truly analytic, work. It may also serve a very valuable purpose indeed as proof of the fact that a text in the social sciences can be written with brilliance, and captivate the interest of the reader. Information collected from the four corners of the earth must be used for scientific purposes with the greatest caution, but it does give the thesis it illustrates liveliness and colour for all that. By no means the least of the merits of this abbreviation of the text is the extent to which it preserves the literary qualities of the original work.

T. S. SIMEX

PROGRESS IN THE STUDY OF VISION

Physiology of the Retina and the Visual Pathway
By G. S. Brindley. (Monographs of the Physiological Society, No. 6.) Pp. xi+298. (London: Edward Arnold (Publishers), Ltd., 1960.) 35s. net.

THIS thoughtful and provocative book provides a critical synthesis of the present state of a wide range of visual physiology and biochemistry. Its primary interest is with human vision. Though written by one of the younger workers in the field, it is in large part concerned with matters with which he has already established direct experimental contact; for since 1952, when his first papers appeared, Dr. Brindley has made important contributions in many areas of visual investigation.

A special characteristic of the present volume is its attempt to formulate explicitly the logical structure that underlies areas of sensory investigation in which most previous workers, with notable exceptions, have been content to muddle through to whatever solutions seemed reasonable to them at the time. This is a noteworthy and laudable effort, bound to have an effect, however time deals with the specific

arguments. Indeed Brindley makes no attempt to create an illusion of finality. He is anxious to expose whatever argument he makes in all its strengths and weaknesses, frequently stressing the latter. The field of vision is now developing rapidly, and the present volume maintains a continuous impression of work in progress. Again and again Brindley leads the reader into some present puzzle, and ends with the reassurance that, judging by the present rate of progress, more clarity may be expected shortly.

Perhaps I have already conveyed the impression that this is a highly individual view of the subject. It is perhaps the most wide-ranging attempt to produce order in this field, by a consistent exercise of logical rigour tempered with good sense, since Helmholtz. Indeed my few complaints in reading the book came from the occasional sense of being shut out. Brindley now and then, though rarely, announces some awareness that the reader is presumed to share, since no attempt is made to explain it, but which the person whose work is under discussion apparently missed. A good example occurs on p. 199, where Newton is said to have "published a diagram for predicting the results of colour mixture which, if it were exactly valid (which it clearly is not), would imply trichromacy... Newton... did not point out its implications". What sticks here is the "would imply trichromacy". Newton's diagram had seven components, to simulate the seven tones of the musical scale. Brindley sees an implication of three primaries, probably with good reason, but does not stop to explain.

Another such passage strikes closer to home. On p. 184 Brindley says: "A mechanism which would achieve something like a suitable relation was suggested by Wald (1954): a rod might consist of many compartments, each inactivated by the photolysis of any one of the molecules of rhodopsin in it. In its original form, this suggestion is contradicted by the very data that Wald used to support it". I should certainly like now to change some parts of my original presentation of this theory; yet I do not know what contradiction Brindley has in mind, and he does not say.

The book opens with what is, on the whole, an expert and searching review of retinal chemistry. This chapter, and Chapter 3 on the central pathways of vision, represent areas with which Brindley has had least direct contact; yet here as elsewhere in the book he presents a valuable critical synthesis of the data. Chapter 2 discusses the electrical activity of the retina. Its main points are the acceptance of Brown and Wiesel's identification of Bruch's membrane as the high-resistance structure across which the electro-retinographic potential is built up, replacing Brindley's earlier idea that this is the external limiting membrane; and Brindley's present conviction that the bipolar cells of the retina are the dominant source of the electroretinogram.

Chapter 4 introduces the discussion of the sensory experiments that occupy the remainder of the book, with an analysis of the logical structure underlying such experiments. All such observations involving reports by experimental subjects contain psychological as well as physical components, which must be connected, implicitly if not explicitly, by what Brindley calls "psychophysical linking hypotheses". He distinguishes class *A* observations, which involve only statements of equality or non-equality of sensations, from class *B* observations, in which a sensory judgment must be made, demanding some

special evaluation, interpretation, or abstraction from the total experience. Brindley discusses the limits of usefulness of class *B* observations, and ways of improving their status. He then applies this logical apparatus to the analysis of a variety of entoptic phenomena, after-images, contrast phenomena and electric phosphores (Chapter 5); functions involving visual thresholds and adaptation (Chapter 6); and colour vision (Chapter 7).

Brindley characterizes this volume in his preface as "a tightly written book, very full of information and for this reason not easy to read from end to end consecutively". This is fair enough, though I should add that it repays handsomely whatever trouble one takes with the reading. A few typographical errors at times make special trouble: in Fig. 2.4 (p. 50), the legend says 155 μ when it means 255 μ ; and in Fig. 2.14, the legend should read "In *a*, taken at 140 μ from the outer ends of the receptors, a large response is recorded from the *inner* pipette, but almost none from the *outer*".

GEORGE WALD

THE SEPARATION OF ISOTOPES

Electromagnetic Isotope Separators and Applications of Electromagnetically Enriched Isotopes

By J. Koch, R. H. V. M. Dawton, M. L. Smith and W. Walcher. Pp. xi+314. (Amsterdam: North-Holland Publishing Company, 1958.) 26.50 guilders.

THE separation of isotopes on a large scale was achieved by several methods during the Second World War as a necessary stage in the manufacture of the atom bomb. Of the various methods employed the electromagnetic separator (calutron), based directly on the mass spectrograph principle, was able to be brought to the production stage earliest. The uranium-235 for both the Alamogordo test explosion and the Hiroshima bomb came from the electromagnetic separators. After the War the far more economical gaseous diffusion process was brought into large-scale production so that the calutron process became redundant for the production of uranium-235.

Nevertheless, the many uses for comparatively small amounts of separated stable isotopes of a wide variety of elements which can be obtained most conveniently from electromagnetic separators has kept an interest in the subject alive, so that many laboratories all over the world have acquired such separators in recent years. The availability of samples of almost pure individual isotopes greatly facilitates the work of the nuclear physicist in working out the details of nuclear interactions, in assigning activities to particular isotopes, and in the investigation of the validity of different nuclear models. It is of importance in spectroscopy where it has enabled the elucidation of the finer details of spectra previously masked by the presence of several isotopes, and where it has made possible the achievement of greatly improved wave-length standards. Such separated isotopes have also been used in solid state physics and in biological studies.

The present work consists mainly of a survey of the construction of such practical separators and of the physical principles of their operation. It also includes a very brief discussion of some of the applications of the enriched isotopes produced by the method. It confines its attention to the calutron type of apparatus

so that it is not comprehensive in the discussion of all types, even of electromagnetic separators. There is no discussion, for example, of the omegatron. It is divided into three parts, each of about equal length. The first part, written by J. Koch, is devoted mainly, but not exclusively, to separators developed largely independently of the American experience gained during the Second World War. These were mainly developed after the War, but since the American experience was not declassified until the early 'fifties, independent development was necessary.

The second part, by R. H. V. M. Dawton and M. L. Smith, is mainly devoted to the description of the Harwell separators which were constructed in full knowledge of the American war-time experience. The method of treatment necessarily entails a considerable overlap between these two articles. They are both concerned mainly with technical constructional details rather than physical principles and will therefore have a rather restricted appeal.

The physical principles of the ion-optical systems employed, the high-current sources and the fascinating problems raised by the space-charge neutralization of ion beams are discussed by W. Walcher in the third section, which will be of more general interest. The book should prove of great use for those interested in designing isotope separators while the third section will be of interest to wider circles of physicists.

E. H. S. BURHOP

EDUCATING YOUNG NATIONS

Educating Young Nations

By W. E. F. Ward. Pp. 194. (London: George Allen and Unwin, Ltd., 1959.) 15s. net.

A MAN who took Beethoven's Fifth Symphony to the Gold Coast thirty-five years ago, and made that music understood, and who to-day writes of the necessity to foster, through education, common nationhoods, which yet respect cultural diversities, has within him a Greek sense of balance and a Christian humanity. These qualities make Mr. Ward's book memorable, kindly and historical. It will be of political and professional value to administrators and educationists working in the newly independent countries of Africa and Asia which have grown up overnight.

Mr. Ward wrote this book in 1959. It is now past history which will interest the newcomers to the field of public service. To those who shared the experience it will provide nostalgic delight. The validity of the thesis that education, particularly the education of a reserve of good teachers, "everyone of whom will be needed when the day of expansion comes", has already been proved. The plea for European technicians to stand by, while the new nations find their feet, is already the theme of the speeches of the more balanced politicians. The proposal that money for education should be looked upon by governments as aid to development rather than to welfare projects, commanding assistance "as if it were a scheme for irrigating the Sahara" is likely to gain the sympathy of the new Ministries of Finance.

Mr. Ward is probably the last author to write contemporarily of "the Colonies" and of "expansion" as a synonym for "independence". His catholic experience of teaching and administering in places as dispersed as the old Gold Coast and Mauritius, his representation of the interests of those countries in the

United Nations, his work as a senior adviser on education to the Secretary of State for the Colonies, give him an authority which will be a reassurance to those still serving that nothing is too difficult for courage and that good human relationships are still more important than politics or race.

The major educational issues with which the book deals—poverty, syllabuses, language, the education of women, selection for secondary work, multi-racialism and teacher-training—will continue to find their various experimental solutions; but the need of humanity for humanity is timeless. There is a charming parable of interdependence in the story of the student offering his notes for a school practice lesson on "The Elephant, a Pachyderm". The apparatus listed was "one elephant, one pin", the latter to prove the toughness of the elephant hide. "Have you your pin?" "Yes Sir, here it is". "And your elephant?" "Sir, as for that, I thought that you could help me".

Mr. Ward points out, soberly enough, that the enormous growth in demand for education, off-set by lessened recruitment from the United Kingdom, is likely to result in a temporary loss of standards in schools. He records the political and social implications of so-called education by teachers who are "mainly chalk and talk" and stresses that, so far as possible, quality should be maintained at the top. One is left guessing at the contents of the unwritten chapter on the influence of the new leadership on education and the length of time during which, with genuine trust and expectation, those who are achieving independence will continue to look to an older order for the production of the elephant.

MIRIAM JANISCH

A HISTORY OF METALS

A History of Metals

By Leslie Aitchison. Vol. 1: Pp. xxi+1-304 (figures 1-127). Vol. 2: Pp. xvii+305-647 (figures 128-282). (London: Macdonald and Evans, Ltd., 1960.) 168s. the two volumes.

"A HISTORY OF METALS" differs from many others on a similar theme, first in that it has been written by one who is a metallurgist of wide experience and high reputation, qualifications not found in all writers on the subject. In the second place, the author has painted his picture against a background of the history of civilization itself, which both provided the conditions in which metallurgy could develop and which, on the other hand, were themselves fundamentally modified by those very developments. The appeal of these volumes should, therefore, be not only to the metallurgist but also to the archaeologist and social historian.

In the author's treatment there emerges little which is essentially novel; in his own words the book is "a fractional distillation" of the work of others. His duty has been to collect facts already known, to sift the wheat from the chaff, and then to present a reasoned, critical account of his harvest. It follows, therefore, that he has inevitably been dependent on others for his original data. Cross-linkages, however, are not infrequently possible which strengthen the main structure and give it a stability in so far as the chief features are concerned. Details, at times even important ones, particularly those relating to the

earlier stages of development, are still uncertain, and not everyone will agree with the author in all particulars. This is perhaps especially true, as he makes abundantly clear, in connexion with any attempt to provide more than an approximation to actual dates.

These volumes cover a period of some six or seven thousand years of which Volume 1 carries the story down to about 1000 A.D. and deals with the seven metals gold, copper, silver, lead, tin, iron and mercury together with their alloys bronze, brass, pewter, steel and amalgams. "Broadly, the several metals and alloys were used for much the same purposes at the end of this long period as at its beginning the evidence of development appearing more in the variety of articles made . . . than in novel applications. As the centuries passed, technological improvements in metallurgical processes were effected and greater weights of material were handled, but during the whole of the . . . years dealt with . . . metals were won and worked by manual power. . . . Appropriately, therefore, Volume 2 opens at the time when power that has not been generated by human muscles was first applied to metallurgical operations", in any event on a substantial scale. The processes by which the metals were extracted from their ores, however, remained essentially unchanged for another two or three centuries at least. As Dr. Aitchison points out, "when the thirteenth century opened, iron—in most parts of Europe and certainly in England—was still being extracted by almost exactly the methods that had been used three millennia earlier" and much the same is true of the other metals.

In the author's view a metallurgical medievalism then occurred which lasted until the beginning of the eighteenth century, though these five hundred years were by no means static. From a craft an industry was relatively rapidly evolved, a medieval industrial revolution. It may well be that Dr. Aitchison's main contribution is to be found in the three chapters which, starting with the Crusades and followed by the discovery of the American Continent, deal with this period.

It is not surprising that an author, most of whose life has been spent in industry, should turn his readers' attention to commerce as well as to technology. His chapter on "Traders from Troy" draws a picture of the commerce of the third millennium B.C. of particular importance from his point of view in its profound influence on the resulting dispersion of knowledge of the technologies in general.

The predominating importance of the metals in moulding and stimulating scientific thought in all ages is reflected in three chapters concerned with this aspect of his history, first in antiquity, then during the birth of modern science and finally in the present era of nuclear transformations. Although the later parts will be well known to scientific readers, Dr. Aitchison justifiably stresses the part played by technological processes and products in the evolution of our scientific and philosophical ideas.

No review of these volumes would be adequate which did not emphasize the author's easy presentation of his material and his skilful avoidance of technicalities. The excellent illustrations have been well chosen, and many, in any event, will be new to most readers: there are a list, comprehensive but not exhausting, of sources for further reference and a good index. The price is high, but those who are able to acquire this book will have a treatise well worth possessing.

F. C. THOMPSON

Sedum of the Trans-Mexican Volcanic Belt

An Exposition of Taxonomic Methods. By Robert T. Clausen. Pp. x+380. (Ithaca, N.Y.: Comstock Publishing Associates, Cornell University Press; London: Constable and Co., Ltd., 1959.) 65s. net.

THIS very thorough investigation of 28 species of *Sedum* growing in the Trans-Mexican Volcanic Belt should be noted by all those interested in modern taxonomic methods entailing population studies in the field and experimental garden as well as the examination of herbarium specimens and literature. The author's conclusions, in his own words, are based primarily on gross morphology and ecology: only limited data about chromosomes, anatomy, embryology, etc., were available. "Such data, when used to overrule conclusions based primarily on details of gross morphology and ecology, should be based on samples sufficiently large to be of statistical significance." His own approach to the problem of sampling and the study of environmental modifications should be read by everyone working on revisions of critical north temperate plants, and his comparison (Chapter 8) of his own work on *Sedum* with that of his predecessors, Berger and Fröderstrom, is revealing. *Sedum* was a good genus to choose for attack by modern taxonomic methods: material is easy to propagate for cultural experiments, and "dried specimens of *Sedum* in herbaria are not reliable for descriptive data, regardless of how valuable they may be for indicating the distribution of species".

N. Y. SANDWITH

Heredity of the Blood Groups

By Prof. Alexander S. Wiener and Irving B. Wexler. Pp. x+150. (New York and London: Grune and Stratton, 1958.) n.p.

DURING the past fifteen years, as the authors point out, knowledge of the blood groups has progressed with great rapidity, and blood grouping has become a fundamental pathological science, knowledge of which is important in many fields. The heredity of the blood groups should be clearly understood, and the authors in this book set out their conception of this; but the book is not solely a study of the inheritance of the blood groups—it contains a good deal of serological information as well, and concludes with chapters on medico-legal applications and anthropological studies.

There is an introduction and then sections on the ABO, MNS, P, Rh and other blood-group systems. The main chapter in the book, however, concerns the Rh-blood group system, and of the 146 pages in the book, about 40 are devoted to this chapter. In it are described the details of the Rh-Hr system of notation and its various applications; anyone who is not familiar with Dr. Wiener's views on this subject will find them clearly set out in this chapter. Some of the other blood-group systems are rather sketchily dealt with, for example, the Lutheran, Duffy and Kidd systems occupying only 1–2 pages each, but in certain instances useful information is given in a condensed form; the Kell system is a good example of this. One of the less-pleasant features of the book is the use of bold-face type for certain of the blood group symbols; it would be better if this were discontinued. In certain of the rarer blood group systems, the authors substitute a notation of their own for that which is more widely and generally accepted by other workers. This, for example, is done

in the Duffy and Kidd blood group systems; it is unfortunate that they have decided to do this.

This is a book summarizing many aspects of work on blood groups and will be of greater interest to those primarily concerned with blood groups than to the general reader.

F. STRATTON

A Text-Book of Metallurgy

By Dr. A. R. Bailey. Second edition. Pp. x+561. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1960.) 30s. net.

THE first edition of this book, published in 1954, was very favourably received because it provided an elementary account embracing almost the whole field of metallurgy, from ore-dressing to the physical behaviour of metals, written in a concise and accurate manner. The general form of this book is retained in the new edition, but the author has made many additions referring to modern developments and has provided an adequate number of up-to-date references. The coverage of the book is so large that inevitably most subjects do not receive great depth of treatment and the level is that of first-year metallurgy at a university or the equivalent stages of a technical college course. It is a good preparation for the more specialized texts which must be used at a later stage. In any technological subject, a balance must be struck between basic theory and practice, and indeed the author of the present book succeeds in blending these two aspects to form a harmonious whole. For example, the student can find in one chapter a simple treatment of dislocations, while in another he can read an admirable account of the various mechanical working processes used in industry. The book is, in the reviewer's opinion, the best of its kind available. It represents in these days remarkably good value for money, and students intending to read metallurgy have good reason to make it one of their first acquisitions.

Annual Review of Physical Chemistry

Vol. 10. Edited by H. Eyring, in association with C. J. Christensen and H. S. Johnston. Pp. viii+537. (Palo Alto, Calif.: Annual Reviews, Inc., 1959.) 7 dollars.

THE latest volume of this well-known publication includes nineteen chapters, fewer than usual but the chapters are longer. Each has a very full list of references, and a notable feature is the inclusion of much Russian literature. The authors are British, Norwegian and American. Besides familiar topics such as thermodynamic properties, electrolytes, heterogeneous equilibria and spectra, there are chapters on copolymers, proteins, nuclear and paramagnetic resonance, and high temperatures. Each chapter covers a wide field of literature; but in spite of detail and the necessarily brief treatment the book can be read with interest and should be intelligible to physical chemists generally. The authors have taken a good deal of trouble in this direction and have been very successful. It is impossible in a brief notice to indicate the contents of the chapters, but I found those on electrolytes and high temperatures of particular interest; other readers will certainly have different choices. This series of volumes should enable physical chemists to keep up to date in fields outside their own particular interests. The book is very well produced and the price is reasonable.

J. R. PARTINGTON

ROCKET AND SATELLITE INSTRUMENTATION

ISTRUMENTATION for rockets and satellites was the subject of a one-day symposium organized jointly by the British Interplanetary Society and the Society of Instrument Technology on September 1. The meeting was held at Manson House, London, and attended by more than one hundred members of the two societies and others. The morning session, at which Dr. W. R. Maxwell, vice-president of the British Interplanetary Society, took the chair, was devoted to papers and discussion of the instrumentation in the space-vehicle, while the afternoon session, under the chairmanship of Mr. C. C. Eltenton, president of the Society of Instrument Technology, was concerned with instrumentation at the ground stations.

The first paper, by Mr. M. O. Robins, of University College, London, formed a very appropriate introduction to the subject since it outlined the British space research programme as constituted in June of this year. In this context he defined space research to mean scientific research carried out by using the technique of rockets, either for vertical sounding of the atmosphere or for the launching of Earth satellites. Historically the British effort started with the first steps taken in the autumn of 1953 by the Gassiot Committee of the Royal Society which resulted in the development and launching of the *Skylark* rocket at Woomera in 1957. This reliable and versatile vehicle has enabled a variety of valuable scientific measurements to be made up to heights of 100 miles and more. These, carried out mainly by university groups, have included investigations of upper-atmosphere winds and temperatures, electron density, solar radiation and cosmic rays. Experiments planned for the near future include measurements of the geomagnetic field, observations on ultra-violet wave-lengths and ionospheric investigations using radio propagation methods.

The effort made in Britain to extract the maximum of scientific information from optical and radio observations of the Earth satellites launched by other countries had been very effective. The data obtained had already yielded new information about the ellipticity of the Earth, air density and the ionospheric regions. The positional information also enabled a satellite 'prediction service' for observers in the United Kingdom to be operated.

Turning to the British plans for the direct use of satellites, Mr. Robins spoke of the arrangements whereby British-designed instruments will be carried in the *Scout* satellites to be launched in the United States, and of the possibility that British satellites might be launched by a rocket system based on the *Blue Streak* and *Black Knight* designs. For the first British *Scout* payload, the main objective of the experimental programme will be the direct study of the electrical properties of the ionosphere. Present arrangements envisage three *Scout* payloads for the United Kingdom, and experiments for the second are being worked out.

Design studies of possible British satellites and of the investigations to be carried out in them are in progress. Three types of satellite are envisaged. The first, which would weigh about 1,750 lb. and go

into a circular orbit of 300 miles height, could carry a telescope and spectrometer for ultra-violet astronomy of stars. The second, of 500 lb. in weight, might be capable of penetrating to distances of 10,000 miles and would enable studies to be made of the Earth's atmosphere, gravitational and magnetic fields. A third and smaller satellite capable of very elliptical orbits is also being considered.

The instrumentation for the first Anglo-American *Scout* satellite was described by Dr. A. P. Willmore, of University College, London. The satellite, which would be launched by a four-stage rocket using exclusively solid propellant motors, would be approximately 20 in. in diameter and would weigh in the region of 100-150 lb. Its orbital inclination would be above 50°, and its perigee and apogee heights about 200 and 600 miles respectively. The responsibility for the instrumentation would be divided between the U.S. National Aeronautics and Space Administration and the British universities; the former providing such parts as the telemetry and power supplies and the latter the scientific apparatus.

In all there will be six experiments on board the satellite: three ionospheric experiments designed to measure the density and temperature of the electrons and the composition of the positive ions, two to measure the intensity of radiation from the Sun in the ultra-violet and the X-ray parts of the spectrum, and in the last the primary cosmic-ray spectrum will be observed. The electron density in the ionosphere will be measured in two ways. In Prof. Sayers's experiment the capacitance of a parallel plate condenser immersed in the ionosphere will be measured at a frequency of a few megacycles per second, and from it the electron density calculated. In the method devised by University College, London, an electrode, consisting of a 2-cm. diameter disk mounted flush with the outer skin of the satellite, is maintained at a potential of 1 V. or so, negative with respect to the ionosphere. By varying this voltage sinusoidally the curvature of the voltage-current characteristic is determined and the density and temperature of the electrons deduced. The experiment to analyse the composition of the positively charged particles employs a similar technique using a spherical probe on a 12-in. long arm.

Ionization chambers and proportional X-ray counters will be used to monitor the emission of ultra-violet light, and soft X-rays from the Sun in order to correlate ionospheric storms with disturbances occurring in the atmosphere of the Sun.

Dr. J. Ring, of the University of Manchester, dealt in more detail with ultra-violet measurements from satellites. The main difficulties of ultra-violet measurement from the ground are due to absorption, scintillations and background radiation produced by the atmosphere and these could be overcome by satellite-borne instruments. There are, however, many difficulties in the design and operation of the instruments, the principal ones being alignment and the recovery of information gained. For example, the examination of a particular star by means of a spectrograph would necessitate alignment and follow-

ing to $10''$, but, even if a resolving power of $1 \text{ \AA}$. over a $2,000 \text{ \AA}$. range were required, a band-width of only 100 c./s. would be needed for the transmission of the data. If, on the other hand, the intensity of the whole sky were to be measured at a given wave-length, then, although there was no alignment problem, the band-width of data transmission required would be many times greater. Dr. Ring described some of the work already done with rockets and satellites, and looked forward to future developments. It is planned to place into orbit an 8-in. telescope with television camera and also 36-in. and 50-in. telescopes. Although the first two objectives may be attained within three years it will probably be ten years before a 50-in. telescope is in orbit. He thought, however, that astronomical observations would really come into their own when manned satellites were launched.

The afternoon session was opened by Dr. B. G. Pressey, who described the ground equipment used for radio observations on satellites at the Radio Research Station of the Department of Scientific and Industrial Research. These observations had a three-fold purpose: to provide positional information, to obtain information from the instruments in the satellite and to study the propagation of the waves transmitted from the satellite. The instrument principally used for satellite tracking is the interferometer, in which the direction of arrival of the radio-wave is deduced from a measurement of the phase difference between the waves received on a pair of spaced aeriels. Equipments for reception on 20, 40 and 108 Mc./s. are installed at the Radio Research Station, and the 'Minitrack' system, developed in the United States, which operates on frequencies 136–137 Mc./s., is now in course of erection on the same site.

The equipment available for the reception and analysis of satellite signals on frequencies from 20 Mc./s. to several hundred megacycles per second was described. It was the general practice to record the signals on magnetic tape—up to four channels simultaneously—and to analyse the records afterwards. Measurement of the Doppler frequency shift was carried out with the aid of a reference signal of high stability, the radio beat-note produced by mixing it with the satellite's signal being measured automatically on an electronic counter. The direct measurement of the difference between the frequency shifts on two signals on harmonically related frequencies was also described.

As an example of the methods of recording and decoding telemetry signals, the extraction of cosmic-

ray data from the signals from *Sputnik 3* was described. The signals, which consisted of a group of four pulses, were displayed on a cathode-ray tube using a linear time-base, and photographed on to a moving film so as to produce a raster type of record. From this record time intervals between the changes in pulse durations could be readily measured, and ray intensities and count-rates calculated. The method used to decode the more complex systems such as that used in *Explorer 7* were also indicated.

A later paper by Messrs. D. J. McLauchlan and T. T. Walters, of the Bristol Aircraft Co., provided a detailed description of the 'Tintape' equipment developed for the processing of time-multiplexed telemetry data from test missile firings. The input is a magnetic tape derived from the Royal Aircraft Establishment 24-channel telemetry system. After separating the channels the equipment interprets the data relative to the calibration-levels and converts them from analogue to digital form. The output is in the form of photographic records and punched cards. Although designed specifically for one telemetry system, 'Tintape' should be capable of reducing data from other systems without extensive modification.

The remaining paper differed from the others in that it dealt with rocket propulsion instrumentation. In presenting it Mr. A. W. T. Mottram, of Bristol Siddeley Engines, Ltd., reviewed the techniques used for the measurement of the performance of liquid-propellant rocket engines. The most important quantities to be measured are thrust and propellant-flow, and these are required to a high degree of accuracy. Measurement of system pressures, flows and thrust under fluctuating conditions demand less accuracy since their purpose is limited to the establishment of engine behaviour and the qualitative assessment of system defects. The prime requirement is for reliability, for which reason the simplest type of instruments were recommended. The best basic-thrust measuring transducer is a rubber-bonded hydraulic capsule with a pressure transducer of the unbonded-wire strain-gauge type. A free turbine flow-meter had proved to be the best for determination of propellant-flow, and Bourdon gauges were recommended for the measurement of pressure.

The symposium provided a useful review of the instrumentation used in satellites and on the ground for investigations of the upper atmosphere. The full texts of the six papers, together with the discussions on them, will be published in the *Journal of the British Interplanetary Society*.
B. G. PRESSEY

SPECTRUM OF RADIATION BACKGROUND UNDER WATER

By GORDON K. RIEL, JOHN P. DOLFIS and DONALD G. SIMONS

U.S. Naval Ordnance Laboratory, White Oak, Maryland

THE investigation of physical phenomena occurring in the sea has, in many cases, lagged behind similar investigations on land and in the atmosphere. This is certainly true in the field of radiations from cosmic rays and other naturally occurring sources. A detailed knowledge of these radiation backgrounds is necessary to evaluate any underwater programme

in which detection of radiation is required. An analysis of the radiation background is especially important, because, while the sea provides some shielding from cosmic radiation, it contains several radioactive nuclides. This work has an added importance since any programme of measurement of radiation which is to be carried out in the sea will be

Fig. 1. Spectrum of natural radiation measured under water

almost invariably of a low-level nature, thereby requiring an extensive knowledge of the background sources present and their intensities. Such low-level counting programmes may include: certain types of nuclear research problems which require low cosmic-ray backgrounds, tracer studies of ocean currents, tracer measurements of corrosion or leakage, measurements of the concentration of radioactive nuclides in sediments and biological specimens, and measurements of the effectiveness of radioactive waste disposal.

Hitherto, the problem of obtaining such information in the sea has been made difficult because of its relative inaccessibility to specialized nuclear instrumentation. Consequently, radiation measurements involving energy analysis were limited to laboratory examinations of samples taken from the sea. These methods, while instructive and useful for particular problems (for example, backgrounds from biological specimens), were inherently unable to present a true picture of the background radiations under the surface of the sea. The recent availability of transistorized, light-weight, multi-channel analysers, however, has made it possible to conduct spectral measurements of γ -radiation and cosmic radiations *in situ*.

The experimental phase of a programme to measure the energy spectrum of background radiation directly in the sea was begun in January 1960. The results presented here are from these tests and represent, to our knowledge, the first such direct measurements of the naturally occurring radiation backgrounds. A scintillation spectrometer consisting of a 5-in. diameter by 6-in. long sodium iodide (thallium)

crystal, and a transistorized 128-channel analyser for pulse-height sorting, was used for this test. The sodium iodide crystal and associated electronics were encased in a sealed probe and lowered from a surface ship by means of cables up to 1,000 ft. long. A single-conductor armoured cable was used to supply voltage to the probe and return the signal to the ship. On board ship the 128-channel analyser recorded digitally the energy spectrum within a pre-selected range.

Fig. 1 shows the energy spectrum of radiation measured under the water. The curve labelled 'Gulf Stream' gives the cumulative results of two tests at a depth of approximately 400 ft., and a third test at about 1,000 ft. The total counting time of these three tests is 21 hr. These tests were conducted in the Gulf Stream near Fort Lauderdale, Florida. Included for comparison are measurements which were made at mid-depth and in the bottom sediment of the fresh-water of Tridelphia Lake, Maryland. Although the surface background is not shown, it was similar in distribution and magnitude to that found in the bottom of the lake. The general trends of the backgrounds obtained in the sea and lake are lower by an order of magnitude than that at the Earth's surface. This, of course, is to be expected because of the shielding that the water furnishes from cosmic-ray events and from naturally occurring radioactive chains.

The spectral results show essentially three major energy peaks at 1.46, 2.6, and 3.3 MeV. and two minor peaks at 1.8 and 2.2 MeV. These energies are present in both the fresh- and sea-water. The most prominent peak is that of 1.46 MeV., which is due to potassium-40. This is higher in magnitude in the sea than in fresh-water. (No correction has been made for the potassium-40 content of the detector probe itself.) The higher activity in the salt-water is due to the fact that potassium salts, being mostly soluble, concentrate in the ocean. It should also be noted that potassium-40 gives the major background contribution of all the radiation sources present by more than one order of magnitude. Thus, if no energy discrimination is used, the radiation detector will be sensitive almost exclusively to changes in the concentration of potassium-40. Below 1.46 MeV., the scattered potassium-40 radiation masks all other sources.

The peak at 2.6 MeV. corresponds to the 2.61 MeV. γ -ray from thallium-208 in the natural thorium-232 chain. Since these elements are primarily present in compounds of very slight solubility, they concentrate in the bottom sediment. Furthermore, some activity can be expected in the shallow lake water due to mixing of the sediment and washing of soils into the lake by ground run-off. Thus, in addition to the higher cosmic-ray background in the shallow water which tends to increase the rate of count throughout the entire spectrum, a further increase in activity in the 2.6 MeV. region was expected in the lake and at lake bottom. This was clearly demonstrated when the probe was embedded 18 in. into the sediment of the lake bottom. Even though the amplitudes of all of the peaks mentioned were increased in the sediment as compared with the water, the increase of the 2.6, 2.2, and 1.8 MeV. radiations from the heavy elements is an order of magnitude larger than that of the 1.46 and 3.3 MeV. radiations.

The small break at 2.2 MeV. is probably due to the 2.2-MeV. radiation of bismuth-214 from the natural uranium-238 chain or bismuth-212 from the thorium-232 chain. Similarly, the break at 1.8 MeV. may be

due to the 1.8-MeV. γ -rays from bismuth-212. These breaks are also due, in part, to the Compton edges from the 3.3- and 2.6-MeV. peaks respectively.

The exact source of the prominent peak at 3.3 MeV. is not known at the present time. Laboratory tests have shown that this radiation exists as a contaminant of the steel pressure vessel itself, and is not a true source present in the water. Measurements are now in progress to check this further and to try to identify this source of radiation.

Events at energies higher than those originating from the naturally occurring isotopes are assumed to be of cosmic-ray origin. The energy spectrum up to 9 MeV. was measured in the Gulf Stream. There were no peaks from 4 to 9 MeV., and the relationship of count-rate to energy as obtained from the spectra in this range can be represented empirically by:

$$N_E = 54 \exp - 0.72E$$

where N_E is counts per hr. in a 40-keV. interval, and E is energy in mega electron-volts.

In the Gulf Stream, the count-rate above 8 MeV. was 240 counts per hr. with 400 ft. of cable, and 70

counts per hr. with 1,000 ft. of cable. Note that the length of cable is quoted rather than depth, since no accurate measurement of depth was available. In the lake, the count-rate above 8 MeV. from 10 to 50 ft. in depth can be fitted by the following function:

$$N_D = 220 \exp - 0.21D$$

where N_D is counts per minute at depth D in feet.

One difficulty in measuring γ -ray spectra under water is that the radiation is partially degraded in energy by scattering in the water. This tends to smear out the radiation spectrum. Therefore, the features of the resulting spectrum are not as sharp as would be obtained with non-distributed sources. The unfavourable geometry makes estimation of the concentration of radioactive nuclides difficult. A new probe designed to improve the counting geometry is under construction. It will be capable of exploring the radiation at depths in the seas beyond the practical reach of cable support. This will be achieved by lowering the new probe with a free-diving vehicle. Further tests are also planned using the present equipment.

THE SENSE OF HEARING

IT is probably true to say that the eye has received, and continues to receive, from both physiologists and psychologists more attention than has the ear. Nevertheless, speech is one of the most important characteristics of human beings, and the sense-organ with which it is heard deserves therefore to be given due honour. A session of Section I (Physiology) of the British Association, held in Cardiff on September 2, took hearing as its central topic, and left no doubt that this sense is as fascinating as any other.

The main feature of the session was the presidential address to the Section by Prof. W. Burns (Charing Cross Hospital Medical School). He considered the response of the ear both to normal and to intense sound, starting by describing the extraordinary sensitivity and flexibility of the organ. It can detect pressure changes in the atmosphere so small that the actual receptor cells are moved through only the diameter of a hydrogen atom, so that any further increase in sensitivity would merely result in the Brownian movement of the air becoming audible; and yet the ear can also operate for short periods at pressure-levels a million times greater. Part of the secret of this extraordinary performance lies in the mechanical linkage which transmits the sound from the ear-drum to the inner ear where the sense-organs themselves are. The bones which form this linkage terminate in a small piston having only one-twentieth of the area of the ear-drum, and this piston therefore transfers a considerable pressure per unit area to the fluid inside the closed container of the inner ear. In addition to this aid to sensitivity, some protection against loud sounds is provided by the mechanical linkage since muscular contractions can increase its resistance to movement when such sounds are heard and so reduce the sound-level actually reaching the sense organs.

The receptors themselves are arranged, as has long been known, along the basilar membrane which lies

inside the coiled tube known as the cochlea. The basilar membrane runs from end to end of this tube, being narrow at the end where the sound enters and wide at the far end: it was of course suggested at one time that it resembled a set of piano-wires resonating independently to different frequencies of sound, but this does not fully correspond to modern ideas. It would seem rather that a change in pressure at the entrance to the cochlea sets up a travelling wave in the basilar membrane which starts at the narrow end, sweeps up towards the far end, getting larger as it goes, and then dies away. The point at which the greatest displacement of the membrane occurs depends on the mechanical properties of the system and thus varies for different frequencies of stimulation. In general, high frequencies mainly affect the narrow end of the membrane while low frequencies involve the entire length.

The sense-organs themselves are cells about the size of a red blood corpuscle, which rest on the basilar membrane with small bristle-like projections (hairs) sticking up into another membrane, the tectorial membrane, which forms a second 'shelf' above the basilar membrane. The displacement of these membranes causes the hairs to be bent. Now there is a potential of about 150 mV. between the inside of the cells and the fluid in which the hairs terminate. The size of this endocochlear potential depends on the extent to which the hairs are bent at the time, and alternating movements of the membranes will therefore produce an alternating potential, the cochlear microphonic, which can be picked up by electrodes in a number of places in the ear. The microphonic follows sound stimulation very closely with no sign of the all-or-none characteristics of the sensory nerve, and each negative phase of the microphonic is followed by the occurrence of nerve impulses in the auditory nerve. It seems likely therefore that the electrical energy stored in the hair cells somehow

produces the firing of the nerve fibres, although the link between the two is still unknown. The stored electrical energy thus acts as a kind of biological amplifier, triggering off considerable effects from a small input of sound energy.

The message in the auditory nerve, then, carries information about the frequency and the intensity of the sound. Different frequencies of sound give rise to maximum stimulation of different hair-cells and therefore of different nerve fibres: at least this is so at frequencies above 2,000 c./s. or so. Below that frequency each wave of the stimulus gives rise to a burst of impulses in the nerve, and the frequency of the impulses therefore conveys information about the frequency of the stimulus. The higher the intensity of the sound, the greater the number of fibres which become active in the auditory nerve: and, at high frequencies of stimulation, intensity will also be reflected in an increased frequency of firing of the fibres.

Perhaps the most important practical implications of Prof. Burns's paper arose from the question of effects of noise on the ear. On the basis of present knowledge, he suggested that special steps must be taken to preserve the hearing of industrial workers if they are exposed throughout their working life to noise above particular levels. The noise should be analysed into octave bands, and protection begun if the sound pressure-level in the octave below 4,800 exceeded 80 db. above the usual arbitrary zero of 0.0002 dyne/cm. The corresponding criteria for successive octaves down the spectrum were 80, 85, 85, and 90 db. If these minimum levels were exceeded, steps should be taken to reduce the exposure of the workers, and to check their hearing regularly by audiometry. Since occupational loss of hearing tends to appear first at 4,000 c.p.s. and spreads only later to lower frequencies, it can be detected and the workers moved to safer employment before the deafness becomes too damaging socially. This is the surest way of detecting the most susceptible people, although it is being widely assumed that the amount of temporary deafness produced by a short experimental exposure to noise may predict the susceptibility to more permanent deafness after long exposure. Above all, it must be realized that occupational deafness is insidious and need not be noticed by the victim until well advanced: nor is it connected with annoyance, being just as dangerous to people who do not object to noise, and conversely being no hazard at the levels reached by many annoying everyday sounds.

Mr. D. E. Broadbent (Applied Psychology Unit of the Medical Research Council) took up the question of noise, and considered those of its effects which do not involve the ear except as the point of entry of the noise. Many of the alarmist reports often spread about these effects are not supported by the evidence: large-scale studies by the U.S. Navy have failed to find any effect on mental health from noise, nor is there much support for the idea that metabolism is higher when working in noise. The sexual performance of rats remains normal after exposure to very high levels, and although the adrenals both of rats and men appear to be active at such levels, there is no evidence of pathological changes as a result. Some recent German researches do suggest a possible effect on the peripheral blood vessels, which constrict in noise, but the chronic effects of this response need further investigation. In addition, of course, there are widespread changes in the body at the onset of an unfamiliar noise, as there are in any new situation.

These changes (increased pulse-rate, lowered skin conductance, etc.) are really a response to novelty, and cannot be used as arguments against noise without putting in jeopardy other stimuli which have the same effect: for example, meeting a strange member of the opposite sex.

The efficiency of mental work is definitely impaired by noises of more than 90 db., but has not been proved to be so by any fainter noise. The effect takes the form of momentary lapses, between which work may be perfectly normal. Mr. Broadbent was particularly concerned to make a distinction between these relatively slight effects on health and efficiency, and the annoyance caused by noise. The latter was very widespread and natural, even though it had no connexion with the former: even animals try to avoid loud noises, and sounds which they associate with pain; and to a behaviourist one object of civilization is to decrease the frequency of those stimuli which are avoided by human beings. Annoyance is thus an adequate reason for noise abatement, and the cause of the latter can only be harmed by exaggerated claims of effects on health and efficiency.

Dr. T. S. Littler (Wernher Research Unit of the Medical Research Council) then spoke about problems in the testing of hearing (audiometry). Since any complex periodic wave can be regarded as the sum of a number of sine waves, and since the ear does to some extent analyse complex sound in this way, the most developed method of testing hearing is to present to the ear sine waves of various frequencies, and determine the lowest intensity at which they are audible. Since the loudness and pitch of short tones vary with their duration, the test tone must be long enough to avoid these distorting effects: furthermore it must start and stop gradually rather than abruptly, since sharp onsets are heard as clicks and do indeed contain frequencies widely different from that intended. The whole test tone therefore, including its gradual beginning and end, should last at least two seconds.

The intensity of a threshold tone can be specified either as the minimum audible pressure or the minimum audible field: the former term means that the sound was delivered by head-phones and the sound pressure-level, produced by the head-phones, measured. The minimum audible field means that the sound was produced by loudspeakers and the level measured in the position where the listener's head was later to be placed. The two measurements will not usually be the same, partly because of the physical differences in the situations, and partly because of the sound of the listener's own pulse and similar disturbances which are more notable with head-phones.

There will not, of course, be found a definite intensity at which sounds change from inaudible to audible: over a certain range, the proportion of test tones heard will increase as the sound pressure rises, and the threshold is best taken as the level at which 50 per cent of test tones are heard. This level can then be compared with that for normal ears: it has been difficult to get adequate measurements of normality, because samples of the general population are liable to include people with slight undetected hearing loss. But recent measurements at the National Physical Laboratory, and by the Royal Air Force, have provided an adequate reference against which any given person can now be compared.

To some extent deafness due to failure in the mechanical linkage of the middle ear can be distinguished from deafness due to damage to the sense-

organs themselves or later stages in the nervous system. This is because audiometry by bone conduction will show no loss in the case of damage to the middle ear. But bone conduction is less well standardized than air conduction. The same may be said of speech audiometry, in which words are presented for identification at various sound pressure-levels: in this case it may in some people be impossible to obtain perfect performance even at levels well above

the threshold, and it is clear that the performance of the ear at supra-threshold-levels needs further investigation.

The tenor of the whole session was summed up by Lord Adrian, who, in the discussion, reminded the meeting of Darwin's difficulties in explaining the eye on an evolutionary basis because of its complexity. The ear may well inspire similar feelings of admiration.

D. E. BROADBENT

EDUCATION OF SCIENTISTS

THE respective roles of the universities, colleges of advanced technology, research institutes, and other institutes of higher education in promoting the education of scientists were extensively considered at a meeting of Section L (Education) of the British Association for the Advancement of Science on September 1.

Prof. M. W. Thring dealt with the role of the universities in teaching technology. He emphasized that technology has two aspects: that of applied science, which aims at presenting methods of working out rough-and-ready design formulae based on first principles, and engineering, which is concerned with accurate design based on more empirical formulae. The essential difference between pure and applied science is in the aim, and not in the quality of thought or level of fundamentality, the aim of pure science being essentially inquisitiveness, and that of applied science the benefit of mankind. The fundamental aspect of applied science is the development of the coefficients in the differential equations describing the separate parts of the complex processes that occur in industry. The superficial, or descriptive level of applied science is the *ad hoc* solution of practical problems. The corresponding level of pure science is natural history, empiricism, or classification, while the more fundamental aspect of pure science is the *experimentum crucis* to decide between rival theories. Since the only valid 'snobbishness' is that relating to quality of thought, it is unfortunate that many schools have inherited the older idea that there is a 'snobbishness' between pure and applied science. The basic problem is to relate the choice of subject of the students of university standard to the careers which are available for them when they have graduated. There is a great tendency for a boy to choose a subject that he has learned at school, or one which his master studied at university, and since very few applied scientists go in for teaching, this does not produce a correct balance in the choice of careers.

The introduction in Britain of colleges of advanced technology improves the channels leading to careers in applied science, but does not help to improve the proportion of the stream flowing in these channels. The essential problem is thus to show the brightest schoolboys that applied science is worthy of their talents and can give them fascinating careers, and is not just a place for those boys who are not deemed good enough for pure science by their schoolmasters. We need many more brilliant technologists on the boards of industry to give a new look to industry. Prof. Thring said that he has direct personal knowledge of industries which rely on foreign countries

for their development work, and always wait until processes have been developed abroad before they take them up in Great Britain. The reason for this is lack of sufficiently brilliant technologists on the boards of the companies concerned.

The increased numbers of boys going to universities in the next decade, which would correspond to 5-6 per cent of any age-group, meant that one has to distinguish clearly between the static and dynamic view of university teaching. The former looks on students as a series of pebbles of predetermined size, and the function of the university is to sieve the larger ones and separate them rigidly from the smaller ones. Such a view does not, however, correspond to the human possibilities of the students concerned. The dynamic view is that all the 5-6 per cent of the age-group are capable of striking sparks of originality and interest, providing the teaching method can bring them out sufficiently. Somehow it is necessary to show the students that both the fundamental scientific laws and the way in which they explain practical processes have excitement and even glamour. So often the choice of a field of work for a student arises quite accidentally because one part of science has a good teacher, when many other branches of applied science could be presented in an equally exciting way. Some parts of applied science are inherently glamorous, such as nuclear fission, electron theory and rocket combustion; other parts require much more careful handling before the student can see the excitement of these subjects. The blackboard and chalk are no longer the only method of arousing the interest of the student. Colour films, television programmes, working models and working diagrams have all to be pressed into service.

In the Engineering Faculty at the University of Sheffield it has been decided that the size of the classes should by all attempts be kept below 50 so as to retain the close personal contact between the lecturer and the students. With larger classes one might just as well have a colour film of a lecture given once and for all by a national authority. Other points which are very important in the dynamic view of university teaching are the introduction of small supervision groups of not more than two or three students for an hour a week, keeping the number of hours of formal instruction as low as possible—the figure of 30 for the absolute maximum is being suggested—and the introduction of research or design-study problems in the final undergraduate year.

Prof. Thring then said that just as industry must have two legs, the production of goods for sale and

the development of new processes and methods to be a viable organization, so a university department must have teaching and research if the teaching is to be at the best possible standard. Hence, the university applied science department must have a strong research school studying the coefficients in the differential equations of the processes that are of interest in applied science, and this teaches the research students to be self-propelling in research. Prof. Thring confirmed that the civic universities are proud of their efforts to make sure that technologists know what is going on in the humanities, but felt that there should be no compulsion in this matter. He regarded the basic unit as the informal discussion group or the coffee party. In the discussion it was agreed that there is a difference between technology and the needs of industry for applied scientists among school-teachers, and various methods of overcoming this were discussed.

Dr. J. S. Tait, of the Northampton College of Advanced Technology, then discussed the role of the colleges of advanced technology in the education of scientists. In the 1890's a number of colleges of technology were formed as a result of Lord Kelvin's views that the universities were not close enough to industry, and those in London were particularly fortunate in that later on they could prepare students for the internal degree of the University of London.

By 1956 the Government decided that it would be sensible to give a small number of selected colleges of acknowledged reputation the opportunity to develop into colleges of advanced technology and discard all their work below university-level. They were to concentrate on producing the high-quality technologists so badly needed by British industry and research organizations. The colleges of advanced technology aim to produce the leaders of to-morrow by giving a good grounding in the applications of science to engineering. The new award of the Dip. Tech. is intended to have the standing of a second-class honours degree, and the colleges of advanced technology are equivalent to the technical universities of the Continent. The Committee of Vice-Chancellors and Principals of the Universities has recommended that holders of the Dip. Tech. should be regarded as eligible for university higher degree courses. The official entry conditions are six subjects in the General Certificate of Education, of which two must be at Advanced Level for grammar school boys, or better than 50 per cent in the Ordinary National Certificate for boys from industry, but of the 700 students taken so far in Dr. Tait's College, more than half have had three Advanced Level subjects at entry, that is to say, they have the minimum university entry requirements. Two-thirds of the total have been grammar school boys, and approximately 15 per cent public school boys. The wastage has only been about 5 per cent a year. The selection has been very severe since industry is paying about £2,000 per student to provide what, in effect, are scholarships without a means test. The student spends from six months to a year in industry before he starts in the college, and this makes a tremendous difference in his mental outlook, giving him a definite aim for his academic studies. The interest of the students in the humanities is fostered by giving them a 2-hr. lunch period during which lectures in the humanities are available. It was emphasized on behalf of the Department of Scientific and Industrial Research that it is prepared to give post-

graduate studentships for work at the colleges of advanced technology, but the only qualification which can be given in this case is membership of the College of Technologists, while there is a tendency among students to feel that the Ph.D. is the only postgraduate qualification to which it is worth devoting two or three years of their lives. Prof. Craig pointed out that the technical universities on the Continent have their students for five and a half years full-time, and he emphasized that there were essential differences between the aims of the colleges of advanced technology and those of the universities, both being concerned with getting fundamental ideas across to the student, but differing in depth and generality.

Sir Patrick Linstead reported on the work of the British Association Committee, of which he has been chairman, on the subject of broadening the education of the graduate scientist. The desire for knowledge has three aspects: the desire to know how things work, the need to open the doors to a professional career in subjects in which the student is vitally interested, and thirdly, the need to be a member of the world and play his full part in society. On one hand, the student is exposed to lectures on outside subjects and told how important these are; on the other hand, the need to concentrate on his specialist subjects if he is to get through his examinations is emphasized to him. The scientist cannot be complaisant if he does not know of the humanities because of the increasing importance of scientists in the world. Inventiveness and scientific wisdom can only be supplied by vocationally trained scientists, but they also need a wider training as more and more of them are rising to top administrative positions.

The British Association Committee has concluded that both schools and universities have important parts to play in widening education beyond the formal teaching. The schools require more time for minority subjects in the sixth form. In the universities he agreed that compulsion was undesirable, but four steps were necessary: first, the reduction in the pressure on the main specialist subject; secondly, greater attention to non-scientific subjects which are, in fact, a necessary part of the specialist subjects, such as the use of English and the introduction of the history of science; thirdly, the provision of cultural events, lectures, concerts and library; fourthly, the generous provision of facilities, libraries of cultural books which do not close at 5.30 p.m., halls of residence with coffee bars, and beautiful surroundings. Sir Patrick also discussed the question of full-time postgraduate courses, which he regarded as very important. He directed attention to the fact that it would be necessary to have relatively small numbers in such courses compared with the undergraduate courses, while the elaboration of materials and lectures was very great. It was therefore essential not to have excessive competition between different teaching institutions, but to distribute the subjects between them. Prof. Craig also wanted more postgraduate courses, both specialized in advanced technology with people returning from industry, and as extensions of undergraduate courses to more advanced mathematical methods and fundamentals. These should be immediately after the undergraduate course. Prof. Craig also felt that the history of science should be taught with day-to-day reference to the subject as it occurred, and not starting from the very ancient beginnings of the science.

M. W. THRING

HORMONES AND THE CONTROL OF ROOT GROWTH*

By PROF. H. E. STREET

Department of Botany, University College of Swansea

THE aspect of the hormonal control of growth which has been most intensively studied is the expansion phase in the growth of shoot cells. The promotion of this phase of cell growth is a characteristic activity of indolylacetic acid, the only auxin which has been isolated from plants and is known to be widely distributed. This emphasis is reflected in the definition¹ of auxins as "those plant growth substances which are characterized by their property of stimulating extension growth of shoot cells in bioassay tests". Current texts of plant physiology have, in consequence, very little indeed to say regarding the natural growth hormones of roots and their role in controlling the growth and differentiation of root cells.

It was from the early studies of the influence of the root tip upon the positive geotropic sensitivity of roots, initiated by Cholodny^{2,3}, that there developed the widely accepted view that the root tip produces an auxin similar to, or identical with, that secreted by the coleoptile of grasses and that the concentration of auxin thereby established in the root cells is supra-optimal for root growth. The subsequent demonstrations of the presence in roots of substances active in the *Avena* curvature test⁴ and their production by isolated root tips, particularly when these are supplied with sugar, supported this view. A number of workers⁵⁻⁷ did, however, report that externally applied auxins are by no means always inhibitory to the growth of seedling roots, and more recently the careful decapitation experiments of Younis⁸ have shown that the removal of the root meristem does not lead to an acceleration of root extension growth although it does, as earlier claimed, reduce the sensitivity of the root to gravity.

New approaches to the study of the hormonal control of root growth have, however, now developed from the application of paper chromatography to the separation of natural growth-active substances^{9,10} and from studies of the growth of excised roots in sterile culture.

Chromatography has been used to study the natural occurrence in roots of both auxins⁹⁻¹⁵ and substances with gibberellin activity¹⁶. The chromatographic solvents used have in the former case been those known to effect separation of indoles, in the latter case to effect separation of gibberellins from naturally occurring inhibitors. Most of the auxin studies have the limitation that the chromatograms have been assayed only by the *Avena* straight-growth test¹⁷; directed, that is, to the detection of auxins as defined by their activity in promoting expansion of shoot cells. The simultaneous use of pea-root segments¹¹ or excised root cultures (Winter, unpublished) as test objects should increase the value of such surveys when working with root extracts.

There is a measure of agreement between different laboratories as to the pattern of auxin activity found

on chromatograms of the 'ether-soluble' fraction yielded by roots^{11,13,15}. The work of Thurman and Street¹⁶ reveals activity at the R_F of the "accelerator α " of Bennet-Clark and Kefford^{10,11} and of indolylacetic acid; elution and rechromatography of the "indolylacetic acid zone" in various solvents strongly indicates the presence of indolylacetic acid. At a higher R_F there is an acidic inhibitory zone which corresponds, with isopropanol/ammonia/water as solvent, to the " β -inhibitor" of Bennet-Clark and Kefford. The chemical nature of both the α and β zones is, however, obscure. Finally, there is activity at the solvent front which, when rechromatographed in 40 per cent ethanol, is shown to be complex and apparently does not contain indolylacetoneitrile in detectable amount. These chromatograms of the preferentially 'ether-soluble' constituents of root extracts have so far only given negative results when treated with various indole and other sensitive spray reagents, which may indicate that the active compounds are present in very small amounts.

When the alcohol-soluble material of roots in aqueous solution is exhaustively extracted with ethyl ether or ethylacetate significant auxin activity remains in the aqueous phase. This 'aqueous' fraction has been submitted to chromatography and bioassay in several laboratories¹³⁻¹⁸, but the published chromatograms do not reveal a consistent pattern, nor have the discrepancies been satisfactorily explained. Thurman and Street¹⁶, by adopting certain purification procedures, combined with low levels of chromatogram loading as compared with those required for the detection of activity in 'ether' fractions, have demonstrated an indole and ninhydrin reactive zone. Part of the growth-promoting activity of this zone is attributable to the indolic amino-acid, tryptophan, and part to other unidentified ninhydrin-positive substances. The 'aqueous' fraction also yields, at a higher R_F in isopropanol/ammonia/water, a broad zone of growth-promoting activity resolvable by rechromatography into discrete growth-promoting ninhydrin-positive zones which do not correspond in R_F with any of the commoner amino-acids. Sugars detected on these chromatograms could be separated from the growth-active zones.

The purpose of describing these results in some detail is to direct attention (1) to the complexity of the picture in these and other studies involving chromatography, (2) to the evidence for the presence of indolylacetic acid albeit at very low concentration, and (3) to the quantitative importance of the preferentially water-soluble constituents, including tryptophan, in the total 'auxin' activity extractable from root cells. To this must be added the recent demonstration by Butcher¹⁸ that tomato roots also contain substances with gibberellin activity as revealed by the dwarf pea assay¹⁸.

The complexity of the indole system in roots is further suggested when one examines by chromato-

* Substance of a paper given before Section K (Botany), at the Cardiff meeting of the British Association on September 7.

graphy (even at low levels of loading) the 'ether' fraction obtained from roots which have been allowed to take up indoles from the external medium. These indoles have, in unpublished experiments carried out in my laboratory by Thurman, been applied at inhibitory but sufficiently low concentrations that the roots can recover from the experimental treatments as shown both by subsequent root growth and depletion of the accumulated compounds on transfer to indole-free medium.

Feeding with indolylacetic acid (10^{-6} gm./ml. for 24 hr.) leads to a marked enhancement of growth-promoting activity at the indolylacetic acid position, to the appearance of Ehrlich and nitric-nitrite reactors and to growth-promoting activity at R_F 0.25 (isopropanol/ammonia/water). The two strong nitric-nitrite reactors at R_F 0.25 and 0.35 in this solvent, can be resolved into three distinct reactive spots by rechromatography in butanol/pyridine/water. One of these has been shown by hydrolysis to be indolylacetylaspargate, the second corresponds in R_F with indolylacetylglutamate and the third the nature of which is unknown gives a characteristic pink colour with nitric-nitrite reagent (the same compound seems to have been detected by Andreæ and van Ysselstein¹⁹ in stem tissue). In addition, the isopropanol/ammonia/water chromatograms showed two other indoles, one at the starting line and the second at the R_F of indolylacetamide.

Feeding with indolylacetonitrile (10^{-6} gm./ml. for 24 hr.) gives high growth-promoting activity at the indolylacetonitrile position, but the only other compound detected was inactive in the *Avena* test and corresponded in R_F and Ehrlich reaction to indolylcarboxylic acid. This suggests the operation here, as in some other plant tissues²⁰, of an α -oxidation of the nitrile via indolylaldehyde without any intermediate formation of indolylacetic acid. Feeding with tryptophan (50 mgm./l. for 24 hr.) leads to the marked accumulation of this amino-acid, but the 'ether' fraction lacks growth-promoting activity (at the low level of loading adopted) and the only ethylacetate-soluble compound detected is probably the malonyl-tryptophan, previously detected in tomato tissue, both as a natural constituent and as a product of tryptophan metabolism, by Good and Andreæ²¹.

Two interesting observations may be noted from these feeding experiments. First, indolylacetonitrile feeding does not enhance activity at the indolylacetic acid position or give the Ehrlich and nitric-nitrite reactors associated with indolylacetic acid feeding. Further, when indolylacetic acid and indolylacetonitrile are fed simultaneously to roots, the resulting chromatogram is equivalent to an indolylacetonitrile chromatogram superimposed upon an indolylacetic acid chromatogram. This suggests that if there is any inhibitory effect of indolylacetonitrile on indolylacetic acid metabolism, as reported by Bennet-Clark and Wheeler²² working with disks of potato tuber tissue, then this is quantitatively unimportant in the root tissue. These new observations, when considered in the light of earlier published physiological studies with indolylacetic acid and indolylacetonitrile^{23,24}, strongly support the view that the activity of indolylacetonitrile on root growth is not explicable in terms of its acting as a precursor of indolylacetic acid. The second interesting observation is that the relatively high levels of indolylacetic acid and indolylacetonitrile and of the indolylacetic acid-amino acid conjugates established in these feeding experiments rapidly decline on transference of the roots to indole-

free medium, suggesting their rapid further metabolism. It should be emphasized that these feeding experiments were only designed to detect major ether-soluble products arising from the absorbed indoles and would not detect protein-indole complexes reported by Seigel and Galston²⁵ to arise from feeding auxins to pea root apices.

As already indicated, 'active' compounds detected in root extracts have been so defined primarily by reference to their ability to promote the expansion of shoot cells. Clearly, therefore, it is important to study the effects of known plant hormones and chemically related compounds on root growth. Using root cultures growing under sterile and defined nutritional and environmental conditions the physiological activity of such substances can be readily described in terms of root morphology, cell division, cell expansion and tissue differentiation. Comprehensive studies of this kind have already been initiated with indolylacetic acid and indolylacetonitrile and revealed their contrasted effects on cell division and cell expansion^{23,24}.

One of the problems raised by such studies was that auxins seemed to be, at sufficiently low concentrations, inactive, and at higher concentrations only inhibitory to root growth; a situation which took us back to the Cholodny hypothesis that auxins function only as inhibitors of root growth. Recent work^{26,27} has, however, shown that appropriate manipulation of the nutritional conditions of culture, particularly in respect of the carbohydrate status, enables significant enhancements of root growth to be obtained in response to treatments with auxins and also with gibberellins and kinetin. Further, since the standard conditions of root culture have been worked out in relation to a very few species, in fact primarily from work with certain tomato root clones, it is not surprising that the bringing into culture of the roots of new species, under probably sub-optimal conditions, has also served to show that very marked stimulations of root growth can be obtained from the applications of low concentrations of auxins and related compounds^{28,29}.

Work involving the application of mixtures of auxins, gibberellins and kinetin to root cultures has shown that the rate of growth, the relative contributions of cell division, expansion and differentiation to growth, the degree of apical dominance and so on are, under certain conditions, determined less by the concentration of any one factor than by the balance between them³⁰. Comparative studies between species of the factors controlling the persistence of meristematic activity in root apices also point to the operation of more than one hormonal factor³⁰. These physiological results, when considered against the background of the complex picture revealed by chromatography, suggest that in root growth and differentiation the balance between a complex of growth factors may be determinative in a way similar to that so dramatically exposed by Skoog *et al.* in their studies on growth and differentiation in shoot callus cultures³¹.

Recently, in work with cultures of cereal roots, there has been obtained evidence of a further aspect of the hormonal control of root growth. Roots of cereals have, in general, proved resistant to culture³². Root tips excised from seedlings, when transferred to standard root culture media, show initially a high growth-rate, but this declines rapidly and ceases within 2-3 weeks. Subculture of the root tips enhances this decline and clones cannot be established in culture.

However, Roberts and Street²⁸ succeeded in establishing clones of excised Petkus II rye roots by incorporating tryptophan into the culture medium. Further, the observation that, in this case, D- and L-tryptophan and indolylacetic acid were all equally effective suggested that the active substance was not tryptophan itself but some compound for which it acted as a precursor. This view was strengthened when it was found that tryptophan samples, if incorporated aseptically and without heating, were either inactive or of very low activity and that activation occurred during autoclaving. Rye roots apparently ceased growth, in the absence of hormonal concentrations of a tryptophan derivative, for lack of some essential growth hormone.

In unpublished experiments, Scott, Carter and Sutton have now studied the growth in culture of excised roots of the Atson variety of wheat and found that the level of growth and its persistence can be dramatically enhanced by illuminating the cultures. Further, that autoclaved tryptophan very nearly reproduces in dark-grown cultures the enhancement of growth achieved by illumination. In this case, however, indolylacetic acid does not effectively substitute for tryptophan; the wheat roots are apparently much less able to metabolize indolylacetic acid to the required active compound.

Now it is known that, under certain conditions, the growth of excised roots of maize²³, *Lycopersicon pimpinellifolium*²⁴ and tomato²⁵ is also enhanced by low-intensity illumination, and work on the action spectrum of this light effect with both tomato and wheat indicates a peak of activity in the red. This work prompts me to ask whether light is an essential requirement for the growth of all roots in culture; in which case the roots of most species so far successfully cultured presumably receive sufficient illumination during the manipulations involved in subculture to permit active growth during the subsequent dark incubation period. If this is so, then it can be suggested as one possibility that the growth of roots normally depends on the translocation to them of some specific hormone synthesized in the shoot; the photochemical synthesis of this hormone can, however, also be achieved in root cells exposed to light. In the light-responsive excised wheat root we may have a system in which it will be possible to characterize and study the biosynthesis of the hypothetical 'rhizocaline' (root hormone supplied by the shoot) first so called by Bouillene and Went²⁶ but afterwards invoked by a number of workers.

This review, despite its incompleteness, may nevertheless have shown that our knowledge of the hormonal control of root growth has reached a point

which could lead to very fruitful further research. This will, however, require the isolation and identification from root extracts of active hormones which, on present evidence, can be expected to be present in very low concentrations; the isolation of the enzymes concerned in the synthesis and metabolism of these growth hormones and the intensification of physiological studies. If such studies are to be pursued with sufficient intensity to have a successful outcome it will require a considerable re-orientation of the research resources at present devoted to the study of what may be broadly called the field of plant hormone research, a field in which extensive practical applications are based upon a most slender body of fundamental knowledge.

OBITUARIES

Mr. A. L. Hetherington, C.B.E.

ARTHUR LONSDALE HETHERINGTON, who died on August 21 at the age of seventy-eight, was educated at Highgate School and Trinity College, Cambridge. On leaving Cambridge, he taught for two years at his old school and then served for two years in Burma in the Indian Educational Service. He returned to Britain in 1908 as a junior examiner in the Board of Education. He acted as secretary of

the Board's Advisory Committee on University Grants and as assistant secretary to the committee which framed the scheme of reconstruction for the University of London. During 1914-19 he was secretary of the Carnegie United Kingdom Trust.

In 1919, Hetherington was appointed to the Department of Scientific and Industrial Research, but was immediately loaned to the Treasury to act as secretary of the newly formed University Grants Committee. He was promoted assistant secretary in

1922 and until his retirement in 1943 was in charge of the grants to postgraduate students for training in research, to individual research workers and the grants to the co-operative research associations. He thus assumed responsibility, without any industrial background, for the research association movement in Britain at the most critical and difficult period of its history.

The novelty of this scheme for Government assistance to research in industry was wearing off, and the post-war boom years were coming to an end. Industry was generally indifferent to science and often suspicious of the co-operative aspect of the associations. Money was tight both in industry and Government, and the associations were compelled to function with very limited resources. Most of them were doing useful work, as evidenced by the book Hetherington wrote with Sir Frank Heath on their early history; but the results achieved were seldom of a kind to make a ready appeal to industrialists imbued with a profound faith in traditional methods. It was largely due to Hetherington's skill as an administrator and to his personality that the movement survived these lean years to play a notable part in the Second World War. His work demanded much tact and patience—virtues which did not come to him naturally. It was a great satisfaction to him to see the associations expand after the War to occupy the important position in British industry they hold to-day.

Hetherington's early training fitted him admirably to deal with the scientific grants to individuals; but even here he had his difficulties, as during the 30's more than one influential, but unenlightened, Civil Servant made no secret of his opinion that many of the grants, especially those for training research students, were little more than unemployment doles.

Hetherington's official work was lightened by two hobbies. The first was his keen interest, as collector and expert, in Chinese porcelain. In this field his important book, written with R. L. Hobson, on "Early Ceramic Wares of China" brought him an international reputation. He also took a leading part in the formation of the Oriental Ceramic Society. His second interest was in turning on the lathe. Here recognition of his skill led to his becoming a Master of the Turners' Company, the honorary freedom of which was bestowed on him in 1932. He took special interest in the turning properties of many little-known Empire timbers.

Finally, Hetherington had quite a talent for versification, and frequently amused his colleagues with mildly satirical verses on matters of topical interest to the Department of Scientific and Industrial Research.

O. F. BROWN

Dr. W. D. Douglas

THE death on August 5 of Dr. W. D. Douglas removes another of the now thinning ranks of first-generation aircraft scientists. He was born in Ireland on August 2, 1887, and educated as an electrical engineer at Trinity College, Dublin. For some years he served as a hospital X-ray operator, and then joined the staff of the Royal Aircraft Establishment and specialized in the properties of materials, especially timber and adhesives, which were the common materials of aircraft structures. He became a leading authority on their properties.

In the 1930's, he was in charge of the mechanical testing of aircraft structures and components and materials. Under his guidance the science of testing large structures grew from small beginnings to something like its present degree of sophistication. His advice on the design and strengthening of structures was eagerly sought by aircraft designers.

Douglas's knowledge of the mode and cause of failure of materials was invaluable to the Air Ministry's Accident Investigation Department, and it became usual for the pieces of crashed aircraft to be sent to him. After painstaking re-assembly and examination of scratches, dents and fractures, he was often able to decide the sequence of catastrophe and the cause of failure. The techniques he developed form the basis of present-day aircraft accident investigation. Re-organization during the Second World War put Douglas in charge of the Materials Department at the Royal Aircraft Establishment, the three divisions of which covered chemistry, metallurgy and non-metallic materials.

On retiring from the Civil Service in 1946, Douglas joined the furniture firm of Harris Lebus as its first head of research. In this unique position he spent nine fruitful years, asking questions, seeking answers and giving sound advice. He represented the firm on technical committees, and when the Furniture Development Council was started in 1949, Douglas joined its research committee and was most helpful in formulating programmes and in guiding the Council's research officers. He played a major part in the development of the performance tests for furniture, which are now incorporated in British Standard Specifications. Furniture satisfying the standards is marketed under the 'Kite' mark.

Douglas retired from Harris Lebus in 1955, but continued to serve most effectively on the Furniture Development Council.

In personal characteristics he was a modest man, and the most helpful and sincere of friends to those in need; but he could also be a worthy adversary. A devoted husband and father, he leaves a widow and son.

C. GURNEY

Dr. Peter L. Goldacre

DR. PETER L. GOLDACRE, a senior research officer in the Division of Plant Industry of the Commonwealth Scientific and Industrial Research Organization, Canberra, Australia, died after a brief illness on April 16, at the age of thirty-four. Paradoxically, at the time of his death from cancer, he was engaged in incisive and rewarding investigations into the nature of the chemical factors controlling cell division in plants.

Goldacre was educated at Sydney Boys' High School and the University of Sydney. He joined the Division of Plant Industry of the Commonwealth Scientific and Industrial Research Organization, in 1947, as one of the first two plant biochemists to be appointed to this agency. His early work, reflecting his biochemical training, was largely enzymological. He was the first to characterize the 'indoleacetic acid oxidase' complex as being composed in part of a peroxidase. Later, at the California Institute of Technology, where he obtained his Ph.D. degree in 1952, he was instrumental in discovering the activating effect of substituted monophenols on this enzyme complex. During these investigations, he also discovered that 2,4-dichlorophenol is a specific inhibitor

for the enzyme catalase, and thus permits the demonstration of the related enzyme peroxidase in such tissues as the liver, where its presence is normally masked by the preponderance of catalase.

By the time he returned to Australia, Goldacre had become keenly aware that many important questions in biology were not ready for investigation by classical biochemical techniques. He made the important and difficult decision to shift his research emphasis to the mechanism underlying differentiation of plant cells. His experiments on the auxin-induced initiation of lateral roots in cultured excised flax roots convinced him of the existence of a cell division inducer (kinin) elaborated by the inhibited, pre-existing lateral root primordia. His search for rich sources of kinin-like materials in tissues undergoing cell division led to the discovery of 'Kineapple' (*Nature*, 184, 555; 1959), a yet uncharacterized, highly active inducer of cell division from young apple fruitlets. In collaboration with several colleagues in Canberra, he was attempting the isolation of this material from

three-quarters of a ton of apple fruitlets at the time of his death.

Peter Goldacre's outstanding characteristics were his honesty and easy-going informality, together with his impatience with pretension and sham. He loved camping and the outdoor life; he had a powerful physique and excelled at swimming and other sports. Six months before his fatal illness, he had attended the Fourth International Congress on Plant Growth Regulation at Yonkers, N.Y., and appeared in vigorous good health. The sudden knowledge of his impending death did not materially alter his essentially humorous and compassionate outlook on life.

He leaves his wife and three young children, the youngest born only a few months before his death. To those privileged few who knew him well, he will be remembered as one of Nature's noblemen. The tragedy of his early death lies in the fact that he had so much to give to many who had not yet come to know him.

ARTHUR W. GALSTON

NEWS and VIEWS

Education in Industry

THE British Association for Commercial and Industrial Education has issued reports on two of its recent conferences. The first, "Education for Survival", contains the papers presented at the proceedings of the East Midland Group and is noteworthy for a stimulating account of technological education in Britain by Dr. B. V. Bowden, principal of the Manchester College of Science and Technology. The list of members attending indicates that speakers on subjects like the training of non-apprentices and the attitude of trade unions to apprenticeships were preaching mainly to the converted. The Association would perform a valuable service to industry if it could persuade recalcitrant managing directors of the need for training apprentices and others. The second conference dealt with "The Implications of the Crowther Report", and the speakers, who included the Minister of Education, underlined its main findings and recommendations. The value of what might have been a useful report is diminished by its appearance some five months after the Conference. Information about both reports may be obtained from the Director, British Association for Commercial and Industrial Education, 26a Buckingham Palace Road, London, S.W.1.

British Rubber Producers' Research Association

THE current report of the British Rubber Producers' Research Association gives an account of the progress made during 1959, both in the fundamental study of the structure and properties of natural rubber and in the application of scientific knowledge acquired in recent years to the problems of the industry (Twenty-second Annual Report. Pp. 53. 1960). On the fundamental side, work on the biosynthesis of rubber in the tree has been made possible by the installation of a tropical greenhouse at Welwyn Garden City. The attack on this elusive problem includes the study of the structure of the latex vessels by the electron microscope, and the chemical examination of cell constituents. The chemical processes of vulcanization, that is, of the

formation of a network of long-chain molecules, and the converse processes of ageing or network breakdown continue to be the subject of intensive study; progress in this field, though necessarily slow, is continuous. Of particular interest is the elucidation of the mechanism of surface cracking by ozone and the role of anti-ozonants. It is well known that this type of degradation is dependent on the state of stressing of the rubber, and it has now been shown that the effect of the anti-ozonant is to raise the critical stress for crack growth, while leaving the rate of growth above this critical stress unchanged. The somewhat related problem of fatigue failure has been shown to be associated with the growth of flaws having dimensions of the order of 0.01 mm. The report gives examples of the application of the knowledge obtained from these fundamental investigations to the production of rubbers and rubber compounds having more desirable physical and chemical properties. This work is designed to ensure that natural rubber is not left behind in the competition with the synthetic materials now available. The report is available from the Association, 19 Fenchurch Street, London, E.C.3.

Comparative Efficiency of Indexing Systems

A REPORT by Mr. C. W. Cleverdon on the first stage of an investigation into the comparative efficiency of indexing systems, an investigation supported by a grant to the Association of Special Libraries and Information Bureaux by the National Science Foundation, has now been issued by the College of Aeronautics, Cranfield, on behalf of Aslib (Pp. v+166. Cranfield: The College of Aeronautics, 1960). The grant of £10,000 was made in July 1957 for a study of the comparative efficiency of the Universal Decimal Classification, the alphabetical subject catalogue, a faceted classification system, and the Utermann system of co-ordinate indexing, which in this first stage involved the indexing of 18,000 research reports and periodicals in the general field of aeronautical engineering, about half of which dealt with high-speed aerodynamics. The present

report is essentially a factual account of this first stage and any firm conclusions must await the result of using a piece of test equipment in a test programme for which the National Science Foundation has awarded a further grant. Meanwhile besides describing the general organization of the programme and giving a detailed analysis of the problems encountered, the report includes various statistical details and an account of some supplementary indexing undertaken by other organizations and individuals in co-operation. When the test programme is completed it should be possible to analyse the results so as to ascertain in detail the reasons for success or failure in locating information and eventually to state with reasonable certainty exactly what requirements an information retrieval system must meet and propose methods for the design of such a system.

Co-ordination of Research

A VALUABLE means of co-ordinating research in engineering over an 'academic' region is being carried out by the Academic Board for Higher Technology of the Northern Advisory Council for Further Education (Thirteenth Annual Report, 1959/1960. Pp. 32. Newcastle upon Tyne: Northern Advisory Council for Further Education, 1960). The Board has accepted proposals put forward by Prof. W. Fisher Cassie, of the University of Durham, in which he recommended that the institutions for higher technology in the region should be asked to send to the Board their proposals for research projects. In this way, "the Board would be informed of the whole pattern of research and would be able to advise on the use of expensive apparatus and on the possibility of a number of institutions sharing in a research of some magnitude". The Board also accepted recommendations put forward by Prof. A. F. Burstall that more provision should be made for training in engineering design. As a first step a sub-committee was appointed to report on the organization of short courses for designers. Industry will warmly welcome this initiative.

Magnetic Data for the International Geophysical Year

THE 1957 and 1958 volumes of the *Observatories' Year Book* covering the International Geophysical Year have recently been published (Air Ministry, Meteorological Office. The *Observatories' Year Book*. 1957. Pp. vi+120. (M.O. 680.) 50s. net. 1958. Pp. vi+128. (M.O. 681.) 55s. net. London: H.M. Stationery Office, 1960). They contain the autographic records and eye observations of terrestrial magnetism at Lerwick and Eskdalemuir observatories and of atmospheric electricity at Lerwick and Kew. They also contain the log of the auroral watch at Lerwick and a general auroral table for the British Isles. These two volumes have been published out of turn, the otherwise latest volume published being that for 1950, in order to make the fundamental magnetic observations made at the Scottish observatories during the International Geophysical Year available to geophysicists as early as possible. The volumes for 1951-56 are expected to be published during the next twelve months.

The Sarawak Museum Journal

THE *Sarawak Museum Journal*, under the enthusiastic editorship of Mr. Tom Harrison, Government ethnologist and curator of the Museum, is always of interest to many outside Borneo. The current issue

(9, No. 13-14 (New Series), July-December 1959) includes papers on ethnology, history, prehistory, Welfare States, natural history and some book reviews. Notes on "An All-round Museum in a small Country" are as applicable elsewhere as they are in Borneo. Other articles include some carbon-14 datings from Niah caves, an account of the Piltdown forgery from the point of view of orang-utang teeth from Borneo or Sumatra, and notes on cock-fighting, the Dayah national game.

Education In the Primary School

To help teachers in primary schools, the National Union of Teachers is issuing a new series called "Curriculum Studies". The first, "Mathematics in the Primary School", has been prepared by R. A. Swallow, who has specialized in the teaching of mathematics to primary school children over many years. The booklet is clearly written, full of problems which can be presented to children at differing ages, and based on his own experience of children. The second, "Science in the Primary School", explains how science in the primary school should be developed and describes means of doing this. The author, Cedric Griggs, should now follow the sequence of Mr. Swallow's booklet and present a programme of science teaching to develop coincidentally with young children's emerging interests. Both booklets can be obtained from the Schoolmaster Publishing Co., Hamilton House, Hastings Street, London, W.C.1, the former price 2s. 6d. and the latter 2s.

New Technique in Insulation Testing

THE new 'Megger' insulation tester, series 3, mark 3, manufactured by Evershed and Vignoles, Ltd., incorporates some advanced features made possible by new manufacturing techniques and materials. The instrument consists of a hand-driven generator and a direct-reading ohmmeter. The moving element of the ohmmeter consists of two coils, the control and deflecting coils, arranged so as to oppose each other. There is no control spring and the deflexion of the movement depends on the ratio of the currents in the two coils. The turning effort of the new instrument is considerably less than that required for earlier models. A clutch-less nylon gear-train transmits the handle torque to the generator and provides remarkably smooth and consistent operation. In addition to the insulation testing range, the instrument operates over a continuity range 0-100 ohms with a scale of shape permitting readings as low as 0.1 ohm. The continuity testing voltage is obtained from a new miniature generator so that no battery is required and thus constant readiness for use is ensured.

Evaluation and Presentation of Spectro-Analytical Results

IN the pocket booklet entitled "Evaluation and Presentation of Spectro-Analytical Results" the author, A. B. Calder, directs attention to the various types of error which arise in chemical and instrumental analysis (London: Hilger and Watts, Ltd., 1959. 5s. net). The errors are classified into two groups, determinate or constant errors, and indeterminate or accidental errors. Their mathematical treatment is dealt with in some detail and then finally the application of the treatment to various spectro-analytical problems is discussed. Throughout, references are given to fuller treatments,

but sufficient warning and guidance are given to indicate to the reader the statistical nature of certain problems encountered in analytical spectroscopy. The importance of indicating how the errors are distributed in multi-stage analytical techniques and the saving in operational time which can often be attained, without loss of accuracy, by the correct interpretation of the analytical data, are emphasized.

Hydrogen In Jupiter

ALTHOUGH molecular hydrogen has long been regarded as a constituent of the atmosphere of Jupiter, direct spectroscopic evidence has been lacking. Jupiter has a known mass and size, and the resulting calculated mean density is surprisingly low. When this was considered in relation to the central condensation of the planet as determined from the motions of its satellites, it became clear that much of the planet must be made up of a light substance. The surface gravity on Jupiter is sufficient to retain light gaseous elements, and it seemed likely that hydrogen might be an important constituent at least of the outer layers of Jupiter, and perhaps also of the interior. The spectroscopic detection of molecular hydrogen has proved to be extremely difficult, and it is only possible if a very large quantity of hydrogen is present. The detection rests on a few extremely faint lines of the quadrupole rotation-vibration spectrum of the molecule. It has now been accomplished in the spectrum of Jupiter by C. C. Kiess, C. H. Corliss and Harriet K. Kiess (*Astrophys. J.*, 132, 221; 1960), who found four of the quadrupole lines. In their paper the authors also direct attention to an unexpected excess continuous absorption, which is so far unidentified, but which closely resembles a known nitrogen tetroxide absorption. Objections to this identification can be raised on the grounds that the hydrogen would act on the tetroxide as a reducing agent, but no other identification has yet been suggested.

Banana Fruit Development

N. W. SIMMONDS has reported on experiments on the development of banana fruits and seed fertility, various synthetic auxins and auxin-antagonists being applied to young fruits in lanolin emulsions (*Ann. Bot.*, N.S., 24, 212; 1960). Auxins stimulated the formation of edible pulp in both seedy and parthenocarpic bananas and induced varying degrees of seed fertility. Of the auxin antagonists tried, coumarin stimulated parthenocarp and induced seed sterility, three others were not or only slightly active, and thiourea markedly inhibited parthenocarp. Study of the relation between size of mature fruit and seed content indicates that developing seeds stimulate the growth of pulp, and that the amount of stimulation is roughly proportional to the level of parthenocarp. Fruit development in the banana seems to fit in with Luckwill's general scheme of dual hormonal stimulus.

Pharmacology of Psychotropic Drugs

THE number of chemical compounds with an effect on the higher centres of the central nervous system has greatly increased in recent years; and the remarkable properties of some of them have aroused much interest in their modes of action, which are now better understood because of improved knowledge of the physiology of the central nervous system. A paper by the Director of Research, Dumex, Ltd., Copenhagen, examines systematically the effects of some of the better known of these psychotropic drugs

on the various levels of the central nervous system; their antagonistic and synergistic effects; and the relationship between these effects and the effects on other functional systems and on behaviour. Although the picture revealed is complex and there are many gaps, psychotropic drugs fall into certain classes according to the effects they have, and a system of classification could be developed on this basis. ("The Comparative Pharmacology of Some Psychotropic Drugs". E. Jacobson. Offprint from *Bull. World Health Org.*, 21; 1960. 5s., 1 dollar or Sw. Fr. 3.)

Nomenclature of Human Chromosomes

THE discovery that some errors of sexual development and other congenital defects in man were associated with karyotypic abnormalities has aroused considerable interest, and research in this field is growing rapidly. Already four different states of numerical unbalance of the sex chromosomes have been identified, as well as three primary autosomal trisomic conditions, several examples of karyotypic mosaicism, and other cases attributable to reciprocal translocation and to deficiency. Various systems of numbering of the chromosomes have been used by different research groups, making the comparison of their results difficult. A meeting with the object of trying to devise an agreed nomenclature was therefore arranged by Dr. T. T. Puck, of the University of Colorado, and held in Denver during April 9-11. All those who had contributed to studies of human somatic chromosomes up to the end of 1959 were invited to take part and nearly all were able to attend. Prof. D. G. Catcheside (who acted as chairman), Prof. H. J. Muller and Prof. C. Stern were also present as councillors. A system was agreed on and a statement embodying it and other information relating to the identification of human mitotic chromosomes has been published (*Lancet*, i, 1083; 1960). The statement was signed by all the members, who included five from the United States, three from Britain, three from Sweden, one from France and one from Japan, in addition to those already mentioned. It is hoped that the proposed standard system will be generally adopted, and that any who may prefer to use another scheme will refer to the proposed system and show clearly in what way their own system differs.

Bibliography of Indology

THE National Library, Calcutta, has published the first volume of "A Bibliography of Indology" (Vol. 1: Indian Anthropology. Compiled by J. M. Kanitkar. Edited, revised and enlarged by D. L. Banerjee and A. K. Ohdedar. Pp. xi+290. (Calcutta: National Library, 1960.) Rs. 5.00. 8s.). It is in fact a catalogue of more than 2,000 publications on the archaeology and anthropology of the sub-continent, with frequent notes and extracts from reviews describing the contents of the works. Added are author and subject indexes which enable the reader to use conveniently the references. The result is a very useful bibliography, if not entirely complete, particularly on the prehistoric side.

University News:

Belfast

A CONTRACT has been signed between the Queen's University of Belfast and the United States Navy European Research Contracts Office. Under this contract, in the first year, the University will be supplied with a *Deuce* electronic digital computer and

with money for additional research staff. In return, Prof. D. R. Bates, Dr. A. Dalgarno, and several other members of the Applied Mathematics Department will undertake theoretical investigations on some problems of importance to the Advanced Research Projects Agency (on behalf of which the U.S. Navy Office is acting). In anticipation of the signing of the contract the erection of a building for the computer has been authorized and a new lectureship in digital computing has been established. A digital computing unit has been set up with the Applied Mathematics Department, and Dr. Dalgarno has been appointed director of this unit.

Birmingham

THE University has accepted the offers of Harry H. Payne, Ltd., and of the Harry Payne Trust to make further payments of £1,250 per annum and £1,000 per annum, respectively, to the Harry Payne Fund for a period of seven years from 1961. The Harry Payne Fund was established in the University in 1954 with gifts of £1,000 per annum each from Harry H. Payne, Ltd., and the Harry Payne Trust for seven years. The Fund is used to support a lectureship in employer/employee relations. The lectureship is held by Dr. N. S. Ross, senior lecturer in employer/employee relations.

The following appointments to lectureships have been made: Dr. G. M. Bennison (geology); Dr. T. S. M. MacLean (electrical engineering); Dr. D. A. Wilkins (botany).

London

DR. P. E. POLANI has been appointed to the Prince Philip chair of paediatric research tenable at Guy's Hospital Medical School. The title of reader in haematology in the University of London has been conferred on Dr. Sidney Shaw in respect of his post at Charing Cross Hospital Medical School, and that of reader in bacteriology on Dr. H. I. Winner in respect of his post at the same School.

Massachusetts Institute of Technology: Department of Nutrition, Food Science and Technology

THE Food Technology Department of the Massachusetts Institute of Technology is to be enlarged and renamed the Department of Nutrition, Food Science and Technology. Dr. N. S. Scrimshaw, director of the Institute of Nutrition of Central America and Panama and regional adviser on nutrition of the Pan American Health Organization (the Regional Office for the Americas of the World Health Organization), has been appointed head of this Department.

Dr. Scrimshaw, who is at present an adjunct professor of public health nutrition in Columbia University and a visiting lecturer in the Harvard School of Public Health, will assume his new duties on August 1, 1961. He will continue his association with the Institute of Nutrition of Central America and Panama as a technical director.

The Night Sky in November

FULL moon occurs on Nov. 3d. 11h. 58m. U.T., and new moon on Nov. 18d. 23h. 47m. The following conjunctions with the Moon take place: Nov. 5d. 18h., Aldebaran 0.4° S.; Nov. 9d. 00h., Mars 6° N.; Nov. 21d. 15h., Jupiter 5° S.; Nov. 21d. 19h., Venus 7° S.; Nov. 22d. 08h., Saturn 4° S. In addition to these conjunctions with the Moon, Venus is in conjunction with Jupiter on Nov. 18d. 02h., and

with Saturn on Nov. 28d. 07h., on both occasions Venus being 2° S. Mercury is too close to the Sun at the beginning of the month for normal observation, but it becomes visible as a morning star later in the month; it will be visible low in the south-east before sunrise, rising about two hours before the Sun on November 23. There is a transit of Mercury on November 7, partly visible at Greenwich. At ingress, exterior contact takes place at 14h. 34.4m., and interior contact at 14h. 36.4m. Only the earlier part of the transit will be visible in Great Britain; sunset occurs at 16h. 20m. at Greenwich and Mercury leaves the solar disk at 19h. 13m. The last November transit of Mercury was in 1953, and the next will be in 1973. Telescopic aid will be necessary to observe the transit. Venus is an evening star, setting at 17h. 50m., 18h. 00m. and 18h. 30m. on November 1, 15 and 30, respectively. During this time its distance from the Earth decreases from 119 to 102 million miles, the visible portion of the apparent disk is from 0.823 to 0.744 , and its stellar magnitude from -3.4 to -3.6 . Venus is visible in the south-west after sunset. Mars rises at 20h. 05m., 19h. 20m. and 18h. 10m. at the beginning, middle and end of the month, respectively. It is in Gemini, reaching stationary point on November 21 and then beginning to move westward among the stars. Its stellar magnitude is -0.5 and its distance from the Earth on November 15 is 69 million miles. Mars is now a very prominent object and can be seen almost all night. Jupiter is low in the south-west at sunset, and sets about two hours after the Sun. Conditions are unfavourable for observation. Saturn is in Sagittarius, east of Jupiter, and sets about three hours after the Sun. Conditions are unfavourable for observation. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Nov. 6d. 5h. 05.6m., 318 B. Tau. (R); Nov. 16d. 4h. 02.0m., η Vir. (R). R refers to reappearance. The Taurid meteors are active near the beginning of the month, but conditions are unfavourable. The Bielids are active about November 14, with a radiant near R.A. 1h. 32m., Dec. $+43^\circ$. This shower has recently been recovered photographically, and conditions are favourable, so that there is hope that it may again be seen visually. The Leonids are active on November 15-17, conditions being favourable; the radiant is near R.A. 10h. 08m., Dec. $+22^\circ$.

Announcements

PROF. REBECCA C. LANCEFIELD of the Rockefeller Institute has been awarded the third T. Duckett Jones Memorial Award of the Helen Hay Whitney Foundation. The award, amounting to 6,500 dollars, was conferred for "her long and continuing studies which are so largely responsible for the present knowledge of the biology of hemolytic streptococci".

PROF. JOHN McMICHAEL, professor of medicine in the University of London at the Postgraduate Medical School, Hammersmith, has been appointed a trustee of the Wellcome Trust in place of Sir Henry Dale, who retired from the Trusteeship in July 1960, and was succeeded as chairman by the Rt. Hon. the Lord Piercy. Sir Henry Dale will continue to serve the Trust in an advisory capacity as scientific consultant.

ERRATUM. In the article entitled "Dwarf Mistletoes" in *Nature* of October 8, p. 112, the author of the paper surveyed is incorrectly given as "J. Knight"; the paper is in fact by Dr. Job Kuijt.

SCIENTISTS IN THE PUBLIC SERVICE

SPECIAL PROMOTIONS

SPECIAL posts have been created in the Civil Service as in previous years under provisions included in the White Paper on the Scientific Civil Service (Cmd. 6679, 1945) to provide for the promotion of individual research workers of exceptional merit. The promotions were effective from July 1, and include the following.

Deputy Chief Scientific Officer

MR. R. BENJAMIN joined the Admiralty Signal Establishment in 1944. During the following years his many contributions to radio and radar research and development were notable for their remarkable insight and brilliant execution. Promotion was rapid and he became a special merit senior principal scientific officer, in 1955, at the age of 32. By that time he was already established as an international authority on the theory, design and use of circuits in the video and pulse fields. His practical application of this knowledge to the processing and display of information, together with a major contribution to the concept of the accompanying radar, have borne fruit in the latest naval 3-D air-defence system which has been demonstrated with such conspicuous success. In addition to a continuing concern with advanced radar systems since 1955, Mr. Benjamin has been exploring new techniques of automation and computation to be applied to data processing and weapon control in virtually the whole field of naval warfare.

MR. L. G. CARPENTER, head of the Metallurgy Department, Royal Aircraft Establishment, joined the Establishment as head of the Research Section of the Instrument Department in 1937, and in 1940 was responsible for development of the first gyro-stabilized bomb site to go into Royal Air Force use. In 1940 he was transferred to the charge of the Research Section of Armaments Department concerned with bomb fuzes, bomb ballistics and the air-to-ground rocket weapon. In 1944, he was appointed head of the General Armaments Division and in 1946 head of the High-Temperature Materials Group in the Metallurgy Department. This group was the first (1947) in the United Kingdom to prepare titanium in a pure state and determine its properties. He has guided research on metal fatigue, properties of materials at high temperatures, the use of graphite for the hot parts of rockets and as a fuel container for nuclear reactors and the study of gas/solid reactions. His recent personal work has been concerned with the absorption of oxygen and nitrogen by hot titanium and the oxidation of gold. He is at present engaged on the reaction of rarified beams of nitrogen with solid surfaces and the required vacuum techniques.

DR. L. ESSEN, of the National Physical Laboratory, is internationally well known for his pioneer work on precise frequency standards for accurate measure-

ments of frequency and time-interval. His first major contribution, the Essen quartz-ring oscillator, proved greatly superior to any previous frequency standard and to any mechanical clock for precise time-keeping in observatories and standard laboratories. More recently he was responsible for introducing the caesium atomic beam resonator as a natural standard with a frequency stability and reproducibility of 1 part in 10^{10} . With his co-workers in Britain and in the United States he has used it to calibrate quartz clocks and monitor standard frequency transmissions, thereby establishing invaluable data on the performance of quartz clocks and different caesium standards, the propagation of radio signals, variations of the Earth's rate of rotation and the value of the second of (ephemeris) time in terms of the caesium standard. His determination in 1947 and 1950 of the velocity of propagation of microwave radiation revealed the fact, since confirmed by other observers in the microwave and optical regions, that the previously accepted value of the velocity of light was too low by 1 part in 20,000. His work as an experimental physicist has been nationally and internationally recognized by several awards and he was recently elected a Fellow of the Royal Society.

DR. C. TIMMS joined the scientific staff of the Metrology Division at the National Physical Laboratory in 1936. There he worked with Dr. G. A. Tomlinson, whose work on the standards of accuracy of gear-cutting machinery he has since continued and developed. This work played a large part in the marked improvement effected during the Second World War in the accuracy and reliability of naval and marine reduction gear drives. He is now a national authority on all aspects of gear metrology, and recently was invited to give the annual Viscount Nuffield Lecture to the Institution of Production Engineers on this subject. He has also carried out fundamental work in the measurement and assessment of surface finish, and has been largely responsible for the development of the branch of precision engineering measurement referred to as dynamic metrology. Dr. Timms became head of the Mechanisms, Metrology and Noise Control Division of the National Engineering Laboratory in 1950, and is now applying his knowledge and experience to improvement of the performance of machine tools, particularly in the application of precision circular diffraction gratings to measurement and correction of errors.

Senior Principal Scientific Officer

DR. R. N. COX of the Armament Research and Development Establishment has a wide background of research in experimental and theoretical fluid dynamics and is an expert in the field of hypersonics research.

DR. R. G. HOPKINSON is in charge of that part of the Building Research Station research programme which deals with the lighting of buildings; his particular research interest is the psycho-physics of illumination in relation to design for daylighting and artificial lighting. Good lighting has an important influence on building design, and Dr. Hopkinson's work has contributed greatly to the definition of the quality of lighting on a metrical basis.

MR. D. G. KING-HELE of the Guided Weapon Department, Royal Aircraft Establishment, is a versatile mathematician, whose work on satellite orbits is now internationally known.

DR. D. McLEAN of the Metallurgy Division, National Physical Laboratory, is engaged on the investigation of dislocation structure in iron and iron alloys using the thin-film technique in the electron microscope.

MR. E. C. MASKELL of the Aerodynamics Department, Royal Aircraft Establishment, is an outstanding aerodynamics worker, particularly in the field of slender wings and jet flaps.

MR. W. R. PIGGOTT joined the Department of Scientific and Industrial Research in September 1939. After an early association with Sir Edward Appleton in certain special radio projects during the War, he joined the staff of the Radio Research Station and began his studies of the ionosphere for which he is so well known. Mr. Piggott has made an intensive investigation of the absorption of radio waves by the ionosphere, and pursued this and related topics in great detail during the International Geophysical Year: in the latter respect he has made valuable analyses of the observations made at Halley Bay by members of the Royal Society Expedition. His outstanding contribution to knowledge of the upper atmosphere is demonstrated by the numerous papers he has published, including a special report issued by the Department concerning the design of aeriels to take the best advantage of the ionosphere for long-distance transmission.

MR. L. P. SMITH has been head of that section of the Meteorological Office which specializes in meeting the requirements of agriculture and horticulture since 1949. His success in this form of operational research has been noteworthy, and he has made many practical and easily assimilated contributions to good husbandry. His studies have included relationships between weather conditions and the spread of blights and diseases of plants and animals.

DR. N. URI joined the Research Establishment and Experimental Factory, Aberdeen, of the Ministry of Agriculture, Fisheries and Food in 1954 as a Senior Government Research Fellow, and was established as a principal scientific officer in 1956. The applied objectives of his work have been the prevention of deterioration by oxidative rancidity in food, particularly foods with low water content produced by freeze-drying. He has developed a theory on the effect of the polarity of the environment on trace metal catalysis in relation to the onset and speed of oxidative rancidity in fats. He has devised a new method of testing the stability of fats based on metal catalysis. He has also investigated the anti-oxidant properties of naturally occurring substances such as quercetin and the synthesis of new anti-oxidants.

MR. W. WATT of the Metallurgy Department, Royal Aircraft Establishment, is a research worker in

the field of high-temperature materials, especially ceramics and interstitial graphite.

Similar promotions have been made by:

(1) Agricultural Research Council: Senior Principal Scientific Officer

DR. R. A. BRATTY of the Unit of Animal Genetics, Edinburgh, is engaged on work in the common ground between genetics, embryology and reproductive physiology.

DR. R. M. C. DAWSON of the Biochemistry Department, Institute of Animal Physiology, Babraham, Cambridge, works on phospholipids and their metabolism.

DR. R. F. GLASCOCK is head of the Department of Radiobiology at the National Institute for Research in Dairying, Reading, and has specialized in the application of the isotopic tracer technique to biochemical problems.

DR. C. G. JOHNSON is a member of the Entomology Department of the Rothamsted Experimental Station, Harpenden, Herts. He is best known for his work on the aerial dispersal of insects.

(2) U.K. Atomic Energy Authority: Senior Principal Scientific Officer

DR. T. E. CRANSHAW has worked at Harwell for ten years. During the first eight years he worked on extensive air showers produced by high-energy cosmic rays. In 1954 he designed and built the apparatus at Culham Airfield which was the first to use the principle of covering a large area by a lattice of identical units, and with which many properties of air showers were investigated. In 1959, Dr. Cranshaw performed an experiment to measure a possible difference between the charges of the proton and the electron, which was shown to be smaller than one part in 10^{40} . More recently he has worked on the Mossbauer effect and its application to relativistic frequency shifts.

MR. R. D. LOWDE, during his thirteen years at the Atomic Energy Research Establishment, Harwell, has been in particular an exponent of neutron inelastic scattering techniques as a means of studying the solid state. He was the first to demonstrate the crystallographic phenomena that are the basis of the modern neutron-diffraction methods of investigating lattice vibrations and the dynamics of spin systems in magnetic substances. In recent years he has carried through a series of investigations in the theory and practice of these methods; the principal results have been the finding of effects due to 'spin waves' in metallic iron and due to magnetic 'critical phenomena' near the Curie temperature of the same material. In addition to his work in neutronics and magnetism, he has published researches in electronics and crystallography, and many papers on scientific instruments and methods.

(3) Nature Conservancy: Senior Principal Scientific Officer

MR. M. V. BRIAN is officer in charge of the Furzebrook Research Station of the Nature Conservancy. He is well known for his contributions on social insect populations.

ASTRONOMY IN CANADA

THE April and June issues of the *Journal of the Royal Astronomical Society of Canada* (54, 79, 126; 1960) contain abstracts of reports read to the National Committee for Canada of the International Astronomical Union at a meeting held in Ottawa on November 27, 1959. These reports give a comprehensive view of research programmes at present being undertaken by Canadian institutions, and testify to the virility of Canadian astronomy.

The Dominion Observatory at Ottawa has made important contributions to positional astronomy, and this work is continuing. Two programmes are international in scope, being shared by meridian circle observers at fifteen observatories. These are the observation of 1503 *FK3* supplementary stars, and a programme of 3754 *AGK3* reference stars required for the photographic survey of improved positions and proper motions. Much work is done in connexion with the Time Service, including a co-operative effort to determine the relation between Universal Time and Ephemeris Time by direct lunar photography using a Markowitz Moon camera. Work at Ottawa is by no means confined to positional astronomy, and investigations are in progress on meteor astronomy and meteorites, solar physics and radio astronomy. An intensive search of air photographs of Canada has revealed a number of circular features, some of which may be the remains of meteorite craters. These are being studied by geophysical techniques, and in two cases rock cores have been drilled. It is considered highly probable that the craters at Hollerford, Ontario, and Deep Bay, Saskatchewan, are due to meteoritic impact. An 84-ft. radio telescope has been erected near Penticton, B.C., and installation of equipment is in progress. A programme on 21-cm. hydrogen radiation will soon be undertaken.

At Queen's University a modest programme of astronomical research has been started. Measurements on the scintillation of radio sources have produced results relating to the ionosphere, to rapid variations of the geomagnetic field, and to radio bursts from the Sun. Much radio equipment is in the course of construction, with the view of counting cosmic radio sources.

The David Dunlap Observatory of the University of Toronto is the leading Canadian institution with a large teaching schedule in astronomy. Recently there has been a marked increase in student enrolment in astronomy courses, and there are at present five students taking the full graduating option in astronomy, and six graduate students. Recently accepted theses have included calculations on the interior structure of sub-dwarfs, and photometric and spectrophotometric studies of visual binaries and the determination of their ages. Some work on stellar radial velocities is still in progress, although no new large programmes in this field have been laid out in recent years. The long-established work on globular clusters is continuing; about 4,500 photographs have been accumulated. Many cluster variable stars have been found and periods determined. A supplementary bibliography on individual clusters is being prepared and will shortly be published. Spectroscopic studies of hot carbon stars have been made, and it has been

shown that the photo-ionization of neutral carbon is probably responsible for the opacity in the atmosphere of *R Coronae Borealis*. Investigations of galaxies have led to the identification of a large near-by cluster of galaxies in Canes Venatici, the recalculation of the absolute magnitudes of supernovae and a redetermination of the Hubble constant of expansion of the universe. The radio astronomy programme at Toronto is varied in nature. It includes the measurement of absolute fluxes of the Sun and of selected sky points, and thermal sources are being developed to provide the calibration of the radiometer.

Several Divisions of the National Research Council are pursuing research on astronomical and related problems. Meteor work has been in progress for many years, and both visual and radio techniques are used. A photographic programme of meteor spectroscopy has been undertaken. Auroral and upper atmosphere research is also in progress. Work in radio astronomy includes regular observations of the total flux of radiation from the solar disk and the measurement of the absolute fluxes from bright radio sources. The existing radio astronomy site near Ottawa is now becoming unsatisfactory because of the large amount of interference arising from the expansion of the city. This has led to the establishment of a new quiet site for radio astronomy in Algonquin Provincial Park at Lake Traverse. Radio astronomical and geophysical investigations are also undertaken at several establishments of the Defence Research Board; most of this work is directed to studies of solar-terrestrial relations, the ionosphere and the aurora.

At the Dominion Astrophysical Observatory at Victoria many astrophysical investigations are in progress. Much time has been given to observations of eclipsing binaries in which one star is a cool supergiant and the companion a smaller hot star. The eclipses last many weeks, and observations at ingress and egress enable the atmospheres of the supergiant components to be studied. Five such binaries have been observed. The outer atmospheres of the supergiants contain local condensations of matter in violent mass motion, with velocities of 20 km./sec., or more, relative to the surface. The supergiants have radii, masses and luminosities of respectively 200, 20 and 3,000 times the corresponding solar quantities. Other cool stars are being observed and their spectra analysed by conventional methods. The hot *O*-type and Wolf-Rayet stars are being analysed. They also show large mass motions in their atmospheres; their atmospheres tend to be unstable, showing shells or halos, and it is likely that matter is ejected from these stars. Variable stars of the β Cephei type are being followed in detail, and cometary spectra are obtained whenever an opportunity offers itself. Much effort at Victoria is devoted to stellar motions. The radial velocities, absolute magnitudes and distances of many early-type stars are being obtained, both for individual stars and for members of clusters and associations. Several long-term programmes of radial velocity observations are also under way. New instruments under construction

include a fast grating spectrograph for the 72-in. telescope and a microphotometer recording directly the intensities of spectrum lines, and a Coudé spectrograph for the new 48-in. reflector is being designed.

An astronomical programme at the University of Western Ontario deals with the photometry and spectrophotometry of peculiar Δ stars. Observations are being made to determine which of these stars are variable and to study the nature of the light vari-

ability. The variations in their spectra are also being studied. A programme of laboratory work on molecular spectra has included the measurement of intensities in many astrophysically important bands, the photography of many bands and the determination of lifetimes of various states. An experimental study of the physical basis of the Hanbury Brown-Twiss intensity interferometer has been undertaken, and further work on this is in progress.

R. H. GARSTANG

THE ROCKEFELLER FOUNDATION

THE President's review from the Rockefeller Foundation annual report for 1959 covers a year of appropriations totalling more than 34 million dollars; 6,769,070 dollars went to programmes in the agricultural sciences, 12,300,071 dollars to those in medical and natural sciences and 4,049,350 dollars to those in the social sciences, while 291 Fellows from 39 countries began advanced study outside their own countries, and 339 other Fellows continued work through earlier awards, besides briefly dealing with the Foundation's operating programmes. Five main topics are discussed. The India International Centre, established at New Delhi in March 1959, with the support of 35 of the 38 universities in India, as well as Government support, is intended to provide a forum for fruitful cultural and intellectual exchange in a congenial setting where foreign and Indian leaders of thought may live together: it should serve as a place where scholars and scientists from Indian universities can meet and live with foreign cultural leaders and provide for more frequent contacts and exchange among the widely scattered Indian universities. A small publishing programme is also planned. Besides a grant of 710,200 dollars for building and selected expenses the Foundation has made allocations of 123,935 dollars for five years towards the operating expenses of the Centre.

To assist the New York University to meet the national needs for research and training defined by the Brooklyn Museum conference as necessary to ensure adequate standards of conservation of the nation's immense art heritage, the Rockefeller Foundation has provided 500,000 dollars towards the initial expenses of establishing a laboratory at the University's Institute of Fine Arts new quarters and, on a declining basis during ten years, towards certain operating expenses. The Foundation has already awarded fellowships to three members of the staff of the All-India Institute of Medical Sciences, in which, it is estimated, the Government of India will have invested the equivalent of more than 9 million dollars by March 1961, as well as six travel grants to members of the faculty and administrators since 1957, and appropriations totalling 300,000 dollars for teaching and research equipment. Still more recently, some 500,000 dollars have been released to meet foreign exchange requirements for the construction of the hospital clinic complex. At September 1, 1959, 50 postgraduate students were enrolled, of whom 40 (selected from 60 applicants) were preparing for teaching and research in the basic medical sciences, but only 13 out of 94 applicants could be accepted for postgraduate studies in the clinical fields. There are now 215 undergraduate students, and the first group

will complete the basic course of study at the end of 1960.

Dean Rusk also directs attention to the unexpected dividends on virtually a world-wide basis which the Foundation's modest agricultural programme, began in Mexico in 1943, is now paying. When the project has been completed, descriptions will have been published of virtually all the races of maize in Latin America and seeds of all races will be in cold storage in three centres in Latin America with duplicate samples in storage in the United States. The seed of these maize races is available to corn breeders in all parts of the world, and the collections, which are serving as models for similar banks involving other crop plants, have been drawn upon extensively and have been widely used by maize geneticists in the United States in connexion with analyses of genetic systems of the maize plant, while classification of the living races of maize has permitted identification of many varieties in the prehistoric collection of maize from archaeological sites. The Foundation has also joined forces with the Ford Foundation in establishing an international research institution to meet the urgent need for rice improvement, and, in co-operation also with the Government of the Philippines, an International Rice Research Institute is being planned on a site adjacent to the College of Agriculture of the University of the Philippines at Los Baños, towards which the Ford Foundation has appropriated 6.9 million dollars for construction and equipment and the Rockefeller 160,000 dollars for operating costs in 1960; the Institute should be in full operation by the end of 1961.

Besides this major advance, the operating programme in agriculture in 1959 saw the inauguration of the Inter-American Food Crop Improvement programme, and as a result in the Central American Corn Improvement Project there are now in the six countries concerned 23 full-time specialists instead of 5 part-time. Development of centres for fundamental research to increase knowledge of varietal improvement, soil fertility, cultural practices and the control of plant diseases is being encouraged. Besides referring to progress in the Mexican, Columbian, Indian and Chilean Agricultural Programmes, Dean Rusk emphasizes the virus research programme of the Foundation for which 1,194,640 dollars was appropriated in 1959, under which 110 agents known or suspected of being arthropod-borne are being investigated, 60 of which fall into four major groups, and very good evidence is available that 84 are transmitted by mosquitoes.

It is becoming increasingly evident that infection of man with an arthropod virus is usually accidental,

and the great problem in the temperate zones is to explain how the arthropod-borne viruses are maintained during the colder months when active insect vectors are scarce or absent. Recent investigations have shown that the young forms of several species of ticks parasitize birds, and it is thus possible that an infected tick could be transported over long distances by migrating birds. The extent and distribution of infections of man with the arthropod

viruses can be determined by antibody survey work, and results of a study of residents of Athens provided evidence that the antibodies persist for at least 30 years following infection. Very valuable information has been obtained in extensive antibody surveys in the Caribbean region and a surprising finding of these immunity surveys is the wide distribution and high rate of infection with some of the recently discovered viruses.

BRITISH AGARICS AND BOLETI

A RECENT check-list of British agarics and boleti* is a logical development from the revised list (1948) of Pearson and Dennis, and embodies a number of suggestions that were put forward in that work. Many unjustified names have been dropped, and a number of new records for Britain have been added. The system used follows in the main that of Singer (1949), thus being narrower than that used in the earlier list. The work is not just the compilation that the title suggests; there are 536 pages in all, including the ancillary accounts, and the work has involved a critical study of actual material of almost three-quarters of the species listed.

Part 1A is a systematic list of genera that will be of assistance to foray secretaries and others who make lists of collections. Part 1B is the check-list proper—an alphabetical list of genera and species with synonyms, misdeterminations, authorities and references. Part 2 is a list of epithets of specific, varietal and formal rank that have been used in the past, and will be of value in translating old names in terms

of the present list. Two papers published in association with the list (Part 3 by P. D. Orton, and Part 4 by F. B. Hora; *Trans. Brit. Mycol. Soc.*, 43, Pt. 2) set out a discussion of taxonomic principles which justifies the treatment given. The view is put forward that genera and species must be accurately fixed as soon as possible, but that as yet we have insufficient information on which to erect varieties and forms. Much useful advice to collectors and taxonomists is given here. Comments on the genera used in the list are given; there is a summary of changes in genera and their subdivisions; validations of new combinations and descriptions of new species are found; and there are critical notes and keys to help understand and use the system.

The work is a massive and comprehensive undertaking, and the authors are to be congratulated on their foresight in visualizing it and on their energy in carrying it to completion. It would be strange if all mycologists were to agree with the decisions taken here: there will no doubt be those who will complain at the changes. But in the long run the sooner a stable and workable system is reached the better. This work is a major step in this direction. D. PARK

* New Check List of British Agarics and Boleti. By R. W. G. Dennis, P. D. Orton and F. B. Hora. Supplement (1960) to *Transactions of the British Mycological Society*.

ENDEMIC AND EPIDEMIC GOITRE IN ITALY

THE almost legendary disease of epidemic goitre re-appeared in 1940 in the Italian Alps and Piedmont, attacking thousands of soldiers in the Province of Cuneo, and in subsequent years spreading to the civil population of the other provinces of Piedmont. It died out in this part of Italy in 1945, but continued to flare up in small foci in Lombardy, Liguria, Emilia, Tuscany and Venetia up to 1948 (*World Health Org.*, 14, No. 8; 1960).

The epidemic appeared in an area where endemic goitre had existed for a long time, raged for several successive years from spring to autumn, affected groups or individuals coming from outside the epidemic areas, and spread to regions from which endemic goitre had disappeared decades before.

The Italian epidemic of 1945-48 affected not only man but also dogs and pigs in some localities. At Monferrato it was shown that goitre appeared both in individuals drinking water from the mains and in those drawing their water from wells and tanks. Most of the goitres disappeared after some months, but some persisted and a few were still visible after some years. Administration of iodine brought no improvement and had no prophylactic effect.

Most of the authors who have studied the Piedmont epidemic admit a relationship between epidemic and endemic goitre. This relationship, however, has been questioned in the case of Tuscany, where epidemics without endemic goitre have been known. An analysis of recent data and of the data available on successive epidemics from the year 1700 have led A. Costa and M. Mortara to the conclusion that the two forms of goitre are diagnostically identical. They emphasize, in particular, the cerebral symptomatology that is clinically manifest to a greater or lesser extent in the two forms, and are inclined to the view that the central nervous system is affected, with elective, but not exclusive, localization in the autonomic centres in the diencephalon. Costa and Mortara consider that the cerebral phenomena manifested in acute epidemic goitre might provide some clues to the cerebral changes that result in the cretinism and deaf-muteness of endemic goitre. An important fact is that endemic cretinism is still to be found in its old sites—the Alps and the southern Apennines, including several surrounding hill and plain areas—but does not appear in association with endemic goitre in the south of Italy. Cretins are rare in the

new generations, and among them myxoedema and dwarfism due to thyroid insufficiency are less frequent.

War difficulties and the comparative lack of knowledge about the symptoms of thyroid dysfunction impeded research at the time of the Piedmont epidemics. Most of the tests were normal. Neutropenia was observed with lymphocytosis, and the blood iodine level was high. No serum antibody to human thyroglobulin was found.

In the Piedmont the uptake of radioiodine is generally greater than normal in the mountain, hill and plains foci of endemic goitre, and the iodine taken up is organically fixed in the thyroid. The excretion curve of radioiodine is slow in comparison with that in hyper-thyroidism. Thyroid clearance of iodine is high, kidney clearance is normal. Body growth, bone maturation, and sexual development in children are the same in endemic and non-endemic areas.

During the epidemics of goitre in the endemic area, the environmental factors traditionally considered to influence the disease—water, malnutrition, deficiencies, consanguinity, and shortage of iodine—all received attention. But none of these factors seems to be responsible for endemic goitre or for the Piedmont epidemics. The epidemic spread gave rise to the hypothesis of an infectious origin, with transmission by an intermediate host favoured by hot weather

—for the epidemics occurred mainly in summer. In Umbria, the heavy consumption of *Brassicae* containing goitrogenic factors, and in mountain areas a diet lacking in proteins and in some essential amino-acids were blamed. Endemic goitre is essentially rural in character, and Costa and Mortara consider that its frequent occurrence in localities where sheep are raised in stables may be more than a simple coincidence. The possible influence of radiation has not been ruled out, but radon has been sought in the atmosphere and in the water, and atmospheric radioactivity has been measured, without any relationship with endemic goitre being found. The iodine content of air and water and the excretion rate of iodine have shown no significant differences between endemic and non-endemic areas.

Goitre is not a static disease in Italy. It was widespread in the last century and the first decade of this century; then its prevalence decreased. It appears now that the descending curve has been arrested. Goitre has become more common in central and southern Italy, and has flared up in localities of northern Italy which had for some time appeared free from it. In certain areas the epidemics seem to have left endemic goitre in their train. The phenomenon of epidemic goitre in Italy has given rise to observations and research that are not paralleled in other countries; but so far its origin remains unexplained.

SOME CHARACTERISTICS OF GEOMAGNETIC MICROPULSATIONS (P_c)

By PROF. J. A. JACOBS and K. SINNO*

Geophysics Laboratory, University of British Columbia, Vancouver

A DETAILED investigation¹ has been carried out on geomagnetic micropulsations recorded by rapid-run magnetograms during the International Geophysical Year (1957–1958), from seventeen observatories as widely distributed geographically as possible (see Table 1). The results from these seventeen observatories were recorded photographically, not only on rapid-run magnetograms with a recording speed of 20 mm. per 5 min., but also on standard speed magnetograms with a recording speed of 20 mm. per hr.

Micropulsations (P_c) are defined as continuous pulsations usually appearing on the daylight side of the Earth, lasting for many hours with periods in the

range of 10–60 sec., and amplitudes of the order of a few tenths of a gamma in middle latitudes. However, if the evidence of all investigators over a wide area is considered, it becomes apparent that these micropulsations do not correspond to a single wave-band but to two wave-bands, the first a shorter-period micropulsation (about 15–30 sec.) and the second a longer-period micropulsation (about 30–90 sec.). Fig. 1 shows the spectrum of micropulsations which have been investigated by several workers from stations all over the world, and clearly illustrates the division into these two different wave-bands.

Fig. 1. Latitudinal distribution of spectrum of micropulsations (P_c) with periods greater than 10 sec. as reported by different investigators from data shown on the right-hand side

Fig. 2. Equi-amplitude contours of micropulsations (P_c), derived from Fig. 1

Typical of longer-period micropulsations were those observed on February 12 and April 2, 1958, which have periods of 33 and 45 sec., respectively. These examples have coherent, synchronous wave-forms over a wide area. It is also worth noting that micropulsations of this type often have amplitudes up to ten gammas or more in polar regions.

A pulsation appeared on May 7, 1958, with a period of about 20 sec. and with maximum amplitude at about lat. 50° . Many similar examples (such as those which occurred on February 8 and May 28, 1958) have been found: they all have in common comparatively short periods (from about 15 sec. to 30 sec.). Those shorter-period micropulsations show different periods at different latitudes, although it is not possible to be definite on this point since the speed of the rapid-run recordings is too slow for any fine resolution.

Combining the results of previous investigations with the distribution in latitude of the amplitude of micropulsations which has been derived in the present analysis, equi-amplitude contours can be drawn as shown in Fig. 2. The different distribution in latitude of the amplitude of the two wave-bands of micropulsations and the geographical variation of period of the shorter micropulsations lead to the conclusion that the longer and shorter period micropulsations are probably caused by hydromagnetic waves in the upper and lower parts of the outer atmosphere respectively.

Between about 2300 and 2400 U.T. on February 12, a series of very intense (longer-period) micropulsations were observed. They continued for about 1 hr. and appear as thick traces on ordinary magnetograms because of the slow paper speed (see Fig. 3). Of special interest are the pre- and post-oscillations of this particular micropulsation. The figure shows clearly the intense pulsation of about 6-min. period

which prevailed during the previous 2 hr. and after the micropulsation. Usually this type of pulsation is observed in polar regions and is frequently associated with micropulsations. They are nearly synchronous over a very wide area, from the Arctic to the Antarctic, and on occasions appear in equatorial regions as well. Moreover, the polarization is nearly linear at each station. This type of pulsation has been designated a long-period continuous pulsation (LPC).

Sometimes beating oscillations of micropulsations, which appear mainly in middle latitudes, occur simul-

taneously with these linear pulsations in polar regions. The periods of both the beating micropulsations (P_c) and the pulsations (LPC) are about the same, namely, 3-7 min. (ref. 2). Moreover, the ideal equivalent overhead current-systems which have been drawn for the examples on February 12 are

SMALL-ANGLE X-RAY SCATTERING BY PILE-IRRADIATED GRAPHITE

By W. T. EELES

Central Electricity Generating Board, Berkeley Nuclear Laboratories, Berkeley, Gloucestershire

PREVIOUS attempts to study the nature of radiation damage in graphite by small-angle X-ray diffraction are reported as being unsuccessful¹. This was because the scattering due to radiation-induced defects was small in comparison with that due to defects already present before irradiation. The purpose of the present communication is to report that small-angle scattering of intensity much greater than that found with unirradiated graphite has been observed with specimens of polycrystalline artificial graphite of reactor grade heavily irradiated (*Dido* doses 5×10^{20} – 17×10^{20} n.v.t. measured

thermal flux) at temperatures in the vicinity of 150° C.

The specimens were in the form of solid half-cylinders and were examined in reflexion using a Philips 1050 diffractometer and nickel-filtered copper $K\alpha$ radiation. With $\frac{1}{2}^\circ$ divergence slits the minimum scattering angle (2θ) at which observations could be made was 3° . All the measurements were made under identical conditions. The variation of scattered intensity with 2θ is shown in Fig. 1 for three irradiated specimens and a typical unirradiated specimen. A fourth specimen, irradiated at 300° C., showed no

Fig. 1. Low-angle X-ray scattering from irradiated graphite

increase in small-angle scattering within the observable range of 2θ .

The component of the intensity attributable to radiation damage was obtained by subtracting from each irradiated intensity distribution the intensity distribution of an unirradiated specimen cut from the same block of graphite in the same orientation relative to the direction of extrusion. This procedure compensates for slight block-to-block variations in the pre-irradiation small-angle scattering and also for variations in the degree of preferred orientation. The latter is manifested as differences in the height of the diffuse peak in the vicinity of $2\theta = 11^\circ$ which is due to the short wave-length 'white' X-rays reflected by the 0002 graphite lattice planes. Radiation

Fig. 2. Slope analysis (Table 1: A, $\circ$; B, $\times$; C, $+$)

Table 1

Specimen	Dose (n.v.t. $\times 10^{20}$)	Temperature of irradiation (°C.)	$\bar{R}$ (Å.)	R_{disk} (Å.)	N (per cent)	N (per cent) (n.v.t. $\times 10^{20}$)
A	5.3	150	2.46	3.5	4.3	8
C	17.1	150	2.77	3.9	13.2	7.7
B	15.1	200	2.73	3.9	8.9	5.9

damage results in broadening of the crystalline X-ray reflexions, but in the case of this 'white' radiation 0002 peak the change is very slight and introduces a negligible error into the small-angle scattering curves derived by the subtraction procedure. However, radiation broadening of the copper $K\alpha 0002$ peak in the vicinity of 25° results in major differences which extend as low as $2\theta = 11^\circ$, and as the subtraction procedure cannot compensate for this the curves are in error above this value of 2θ .

The slope-analysis method was applied to the scattering distributions thus derived without making specific corrections for vertical divergence², and it can be seen from Fig. 2 that the plots of $\log I$ versus $\sin^2\theta$ are good approximations to straight lines up to $\sin^2\theta = 0.009$ ($2\theta = 11^\circ$). The slopes of these plots give the average 'radius of gyration' $\bar{R}$ of the scattering centres. Values of $\bar{R}$ are listed in Table 1 together with values of $R_{disk} = \bar{R}/\sqrt{2}$. R_{disk} is the average radius of the scattering centres if they are assumed to be disks of a thickness much less than their diameter. The intensity distributions are not sufficiently accurate to give any reliable indication of the shape of the scattering centres; but it is likely that in irradiated graphite they are disk-like aggregates of interstitial atoms, sandwiched between the graphite layers and formed by clustering of the atoms displaced by neutron bombardment, as already suggested¹.

Interpretation of the present results in terms of this picture presupposes that the observed scattering is entirely due to the clusters of interstitials, and neglects any contribution from the vacancies which must exist in comparable numbers. This is justifiable in that single interstitials probably have a far greater degree of mobility than the vacancies at the temperature of irradiation, and are therefore more likely to form clusters under the influence of the strain fields set up in the adjacent graphite layers. Such clusters of ten or more atoms would have a small-angle scattering power much larger than that of the more numerous single vacancies since the small-angle scattering power of an individual centre is proportional to the square of the number of electrons it contains.

The $\log I - \sin^2\theta$ graphs show little decrease in slope with increase in $\sin^2\theta$, a feature which normally indicates that the scattering centres are all much the same size. In the present case one would expect a range of sizes, but perhaps there is some feature of the mechanism of formation which leads to one size being more probable than any other under given conditions. This size as characterized by R_{disk} increases with dose.

The supposition that the scattering centres are disks of interstitials enables an estimate of their concentration to be made from the absolute magnitude of the total intensity scattered by them, which in the present case was measured by comparison with the integrated intensity of the 002 reflexion of finely powdered rock-salt. The concentration of interstitials, expressed as a fraction N of the number of atoms per unit volume in the perfect graphite lattice, is

related to the total scattered intensity I_{tot} , by an equation of the form:

$$I_{\text{tot}} = KN\alpha R_{\text{disk}}$$

where R_{disk} is the value of the radius given by the slope analysis, α is the number of interstitials/unit area of disk and K is a constant in which are combined various physical and instrumental factors. The value given to α was 0.2 interstitial/ $\text{\AA}^2$, which corresponds to occupation of one in every two interstitial sites within the periphery of a disk, that is, an average distance of 2.44 $\text{\AA}$. between adjacent interstitials. If a higher density is assumed, for example, occupation of every site, the interstitials would be 1.45 $\text{\AA}$. apart and would have to be graphitized to a high degree.

The values of N are given in Table 1 together with the number of interstitials/ 10^{20} n.v.t., which agrees closely with estimates made by other experimental and theoretical methods³. It is perhaps noteworthy that the specimen irradiated at 200° C. shows a lower value of N /n.v.t. than those irradiated at 150° C., a point which it is intended to verify in further experiments.

So far it has been tacitly assumed that the scattering observed here is true small-angle scattering. In several instances supposed small-angle scattering from inhomogeneities in a crystal lattice has since been shown to be multiple Bragg reflexion from distorted lattice planes⁴. Though it is difficult to perform quantitative calculations on this type of multiple reflexion it seems that the intensities observed in the present experiments are at least two orders of magnitude larger than the maximum possible by multiple reflexion. Further, neutron-diffraction experiments⁵ in which the wave-length employed was such as to place all reflexions from

lattice planes beyond the cut-off, that is, $\sin\theta > 1$, definitely indicated the presence of point defects in graphite irradiated to a level comparable with the present specimens. Owing to the difficulties inherent in neutron diffraction, these experiments did not show whether or not the defects were clustered, but the number of defects detected agrees reasonably well with the present ones. Thus it can be argued that neutron diffraction shows that point defects occur in irradiated graphite in sufficient concentration to cause true small-angle X-ray scattering provided they cluster in a manner similar to that postulated here. The observed small-angle scattering interpreted in this way gives a reasonably self-consistent picture which is also consistent with theoretical calculations and other types of experiment.

This work will be continued, and it is hoped that in future the use of plane-polarized X-rays in which the plane of polarization can be rotated⁶ will permit an experimental distinction to be drawn between true small-angle scattering and multiple Bragg reflexion.

I am indebted to the Head of the United Kingdom Atomic Energy Authority's Culcheth Laboratories where this work was carried out, and to the Director of the Central Electricity Generating Board Berkeley Nuclear Laboratories, for permission to publish this article. I also thank Drs. A. L. Sutton and G. K. Williamson for helpful discussions and advice.

SUCROSE CRYSTALS

By H. E. C. POWERS

Tate and Lyle, Ltd., Thames Refinery, London, E.16

Layer Growth

IN an earlier article¹, I was able to report having found that sucrose crystals grew layer-wise, just as Drs. Bunn and Emmett had previously described the growth mechanism of crystals of many salts. I am now able to report that a sucrose crystal immersed in a very slightly sub-saturated solution dissolves by a receding layer mechanism. In a growth cell under the light microscope, one may vary the degree of saturation of the mother syrup by temperature control, and by this means produce advancing or receding layer fronts at will. If a crystal is immersed in very slightly sub-saturated syrup, faint etch pits form first. Later, as the natural gradient of exhaustion of the contact layer becomes established, the receding layers become visible, first near edges and corners, then spreading over the whole crystal surface, and even in the etch pits. I have been able to record this, both by photo-micrography and by ciné-micrography.

Drs. Dunning and Albion² have reported spiral growth in sucrose crystals nucleated and grown under laboratory conditions, but have not hitherto been able to observe them in commercially grown crystals

(private communication). Having now observed a large number of growing and dissolving crystals under the microscope, my impression is that certainly in crystals which have been grown under the practical conditions of varying supersaturation and occasional sub-saturation the layer fronts are so strongly developed as to continue to efface spirals by overgrowth, just as they overgrow pockets of solution in making fluid inclusions. I feel that spirals and layers should be regarded as two distinct, and not necessarily connected, mechanisms by which crystal growth may take place. The latter become more strongly developed with increasing crystal size, also after partial dissolution or mechanical damage. It is becoming increasingly evident that, even on an apparently dry sucrose crystal, the surface should be regarded as in a state of dynamic, not static, equilibrium.

Thin Films

Crystallization in thin films (up to a hundred or so microns in thickness) exhibits different phenomena, according to the nature of the bounding media. These may conveniently be grouped in three cate-

Fig. 1. Mild dissolution: etch pits and receding layers

 Fig. 3. Disordered crystal at 2.4 supersaturation; note spherulitic eruptions
 Fig. 4. Radialite from film, showing part-rhythmic growth
 Fig. 5. An example of rhythmic dendritic exploring growth
 Fig. 6. Sodium chloride grown in vapour-pressure controlled film; whisker, acicular, tabular, etc., forms
 Fig. 7. Radialitic carpet of sucrose from film only one or two microns thick. Note curvature

gories; (a) glass or plastic (relatively inert); thus glass/syrup/glass; (b) atmosphere with controlled humidity (causing migration of water molecules to or from the solution); thus glass/syrup/air; (c) sucrose crystal (offering or receiving sucrose molecules to or from the solution); thus crystal/syrup/air.

(a) The first system has very wide application to problems of form, rate of growth, etc. By adopting techniques on the lines of microbiological work one may avoid intrusion of external nuclei. By warming a supersaturated solution to the temperature of saturation before using, one may seed a film of the syrup, by means of a needle dipped in specially prepared nuclei, without producing fresh nucleation by mechanical hazard. Probably the most challenging demonstration by this system is that of the greatly varying rate of growth of different nuclei when introduced into the same medium. By seeding with two needles carrying different types of nuclei, and with one drawing a horizontal and the other a vertical line, then 'incubating', any difference in the natural rate of growth of the two types of nuclei should be revealed. By this means it appeared that particles of pulverized crystal at first grew more rapidly than whole seed crystals, until the regular crystal form had taken shape. On extending the growth period, however, there appeared far more difference in size between neighbouring crystals of the same origin than appeared overall between those from the different origins.

Another application is to the study of the effect of various impurities on crystal form, for example, increasing proportion of raffinose, which produces first a lengthening in the axis ratio, then striking wedge-shaped forms.

Still another application is to study whether crystals can display any form of 'inheritance'. Can a seed crystal, produced in circumstances favouring a

characteristic form, carry forward the special feature if transferred to a different medium? I have tested this by transferring crushed portions of the spherulitic form produced at high supersaturation to solutions of low supersaturation. The broken edges were repaired, but growth was so slow that normal nuclei, developed in the new medium, rapidly outgrew the spherulitic fragments. An example of internal rather than external specialized form is that reported by Drs. Dunning and Albon², who found spiral growth on crystals nucleated and grown in sucrose solution containing up to 1 per cent of dextrose to have a highly significant heightening of the step as compared with that in pure sucrose solution, hence probably an increased growth-rate. I have not been able by the above means to satisfy myself with evidence of effective 'inheritance' in this case.

By applying non-sucrose components to one exposed edge of an 'a' type film, after seeding, diffusion may reveal the effect of the component thus introduced on the resulting crystallization, as a prelude to a more controlled investigation.

(b) The glass/syrup/air system offers a remarkable facility for attaining and maintaining any desired degree of supersaturation without the handicap of virtually uncontrollable nucleation in the higher range. It also renders possible the production of controlled crystallization in films of thickness down to the millimicron range.

To eliminate rogue nucleation, the solution should be sub-saturated when placed on the slide. Extremely thin films may be obtained by dilution and drainage. The prepared slide is placed in a desiccator, controlled by means of moist salts, glycerine, etc. If the desiccator is suitably constructed, both observation and photo-micrography may be made *in situ*.

Both the natural hazard of nucleation and the resulting crystal form are very strikingly affected by

the degree of supersaturation. With sucrose, nucleation is maximal at about 3 supersaturation, at which stage perhaps one nucleus may form per 24-hr. at 20° C. in a 0.3 gm. film. At less than 1.5 and greater than 5.0 supersaturation, weeks may elapse without a single nucleus forming naturally. Supersaturation has been expressed in the form recommended by the International Commission for Uniform Methods of Sugar Analysis, 1958, namely:

$$\frac{\text{gm. sucrose/100 gm. water at temperature } t}{\text{gm. sucrose/100 gm. water in saturated solution at temperature } t}$$

Regarding the influence of supersaturation on crystal form, at the 1.1 level normal to industrial production, euhedral crystals form. At 1.5 signs of disorder appear, this increasing as supersaturation increases. At 2.5 supersaturation spherulitic multi-crystals appear, together with some abnormal mono-crystals, which by this stage show occasional eruptions of multi-crystal segments, frequently at rhythmic spacing on the mono-crystal. By 4.0 supersaturation practically all nuclei are spherulitic. When grown in a thin film the spherulitic nucleus develops two-dimensionally, that is, 'radialitically', this proving most illuminating on details of structure. Normally, adjoining ray crystals are in harmony of orientation, as with a fan, but the full 360° may include several such groupings, each of different orientation. I have recorded layer growth, also hour-glass and veil inclusions on radialite crystals, just as with normal mono-crystal forms³. My impression is that all these phenomena, culminating in spherulitic nucleation, are the outcome of the build-up of the exothermic heat of crystallization even to the point of local fusion. Mosaic may result from one form of the above disorder.

If the film has been gelled with agar or gelatine the spherulitic nucleation occurs even as low as supersaturation 1.6, and two easily recognized variant forms ensue. With agar, sharply contoured layer growth scales abound; whereas with gelatine, multitudes of gentler curves take the place of the more normal rectilinear radialites.

If crystals are allowed to grow in a thin layer of solution in a covered Petrie dish exposed to atmosphere of 50–60 relative humidity, the upper surfaces of the crystals become exposed. Surface forces cause

solution to be drawn up and continue crystallization, until the residual film is so thin that this flow ceases. Alternatively, one may commence with a film of similar thinness and permit nucleation therein. In either case, the formed crystal then develops an 'exploring growth'—reminiscent of *Amoeba*—which is truly delightful in its rhythmic beauty. Familiar contour angles may be recognized, repeating in nodal and anti-nodal intensity, strongly reminiscent of Liesegang precipitation. A little reflexion on the manner of growth will indicate that each complete pattern, though apparently so complex, is yet as truly a mono-crystal as any simple euhedral crystal. These truly dendritic forms normally develop rectilinearly, but sometimes exhibit curvilinearity, developed by faults, to permit growth to enter a zone richer for growth. This exploring growth can proceed in films so thin as to render crystals invisible in the light microscope, and can develop crystals with truly dry surface areas. It is extremely slow, continuing for weeks.

(c) The crystal/syrup/air system is normally met in industrial application, and will be dealt with more fully elsewhere. It is pertinent to report here that the remarkable ability of syrup to dry almost to the amorphous and extremely slowly crystallizing form, contributes considerably to problems of bulk storage. Probably all the crystal forms described above may be formed during the granulation or drying of commercial sugar.

Though my work has been mainly with sugar, the system of crystallizing in vapour-pressure controlled films, will obviously have wide applications. Sodium chloride so treated has yielded encouraging results. Exploring growth is shown, and whisker growth appears to occur sub-surface, since I have photographed whiskers growing under other crystals. The subsequent development from whisker to needle, also of strikingly clear tabular crystals, is easy to follow and is being filmed, as are many of the sucrose phenomena described herein.

For those interested in this work, a wide and rapidly increasing range of photomicrographs is now available of the diverse forms of sucrose crystallizing under this vapour pressure control.

PROTEINS INDUCED IN PLASMA BY OESTROGENS

By DR. O. A. SCHJEIDE and DR. M. R. URIST

Laboratory of Nuclear Medicine and Radiation Biology of the Department of Biophysics and Nuclear Medicine, and the Departments of Radiology and Surgery, School of Medicine, University of California at Los Angeles

THE fact that at least two—and probably several—of the proteins of egg yolk are synthesized in the liver of the hen and transferred via the blood plasma to the ovary (where they are deposited as granules in the ovum) is well established¹⁻³. However, recent articles by Prof. R. H. Common and Chi-Ching Mok⁴ and Joubert and Cook⁵, convey the impression that much of the data available in the literature, some of it our own^{1,3,7-9}, has failed to come to the attention of workers interested in the eluci-

dation of the proteins involved in avian reproduction. Further, because of the limitations of techniques employed in any single laboratory, much confusion exists with respect to the nomenclature, chemical constitution and physical orientation of these proteins. We have therefore prepared the following critical analysis.

First, the administration of oestrogen to the hen, pullet or rooster results in the amplified appearance of at least three major protein components in the

Fig. 1. Composite ultracentrifuge patterns from plasmas of control and oestrogenized birds. Areas under the peaks are equivalent to concentration. Negative peaks are due to the high proportions of lipid in such fractions. Areas defined by the solid line indicate control values. Those defined by the broken line indicate values for oestrogenized bird. *l*, Light lipoprotein; *m*, mucoprotein; *dl*, dense lipoprotein; *ab*, albumin; *X₁*, *X₁*-phosphoprotein; *g*, globulin; and *X₂*, *X₂*-lipoglycoprotein.

plasma; there are the two mentioned by Common and Chi-Ching Mok (phosvitin and lipovitellin) and also a light lipoprotein varying in flotation-rate upwards from *S_f* 15 (ref. 9). (We have chosen not to apply a generic name to this protein, and have used the term *X₁*-phosphoprotein in place of phosvitin and the term *X₂*-lipoglycoprotein in place of lipovitellin, for several reasons that will become evident.)

The appearance of *X₁* - *X₂* in the serum is not the only change in the plasma of oestrogenized birds. In addition, there are absolute decreases in albumin, globulins, normal light lipoproteins (*S_f* 0-15), dense lipoproteins (*-S* 0-10), and mucoproteins (ref. 9 and unpublished work). The severity of the decreases is proportional to the amount of oestrogen administered and to the increases in components induced by oestrogen. A schematic diagram of these changes as they might appear in a composite ultracentrifuge pattern of chicken plasma is presented in Fig. 1.

Secondly, the implication must be questioned that phosvitin, lipovitellin and a component referred to as γ -livetins⁴ are present in the plasmas in the form of complexes with each other that are similar to the complexes formed when egg yolk or the serums of oestrogenized birds are greatly diluted with distilled water¹. Of course, in the native egg yolk of the hen, the *X₁* and *X₂* proteins (plus lighter lipoproteins and a relatively small amount of nucleoprotein) are present in the form of giant complexes termed granules. (Such granules comprise approximately one-fifth of the total volume of the egg yolk, and on isolation and dissolution with 10 per cent sodium chloride have been demonstrated to contain all the *X₁* and *X₂* in egg yolk³.) However, since the *X₁* present in yolk granules retains a high percentage of bound calcium, the granule complex must be very different from the complex which forms when either plasma *X₁* and *X₂* or egg yolk *X₁* and *X₂* are diluted with distilled water. In these latter cases, the complex appears to result from the removal of naturally bound calcium from the *X₁* phosphoprotein (this phosphoprotein contains 10 times more calcium per unit weight than does casein of milk) exposing numerous negative charges on the *X₁* molecule which readily combine with the positive charges made

available on the phospholipid portion of the *X₂* protein. The amount of calcium associated with serum *X₁* in the native state is sufficient to neutralize the negative charges of the phosphoserine in the molecule so that no complex is formed; and, indeed, phosphorus and calcium analysis of the *X₂* (lipovitellin) component of serum show it to be uncontaminated with *X₁*. As for γ -livetins, its existence has never been demonstrated in plasma or serum.

The term γ -livetins was introduced by Joubert and Cook⁴ to account for a protein component of egg yolk that, when resolved in the ultracentrifuge, trailed behind a fraction which they termed a complex of γ -livetins, phosvitin and lipovitellin (Fig. 2).

Fig. 2. Schematic sketch of egg yolk ultracentrifuge patterns as obtained and interpreted by Joubert and Cook (ref. 6)

These workers claimed that they were unable to resolve γ -livetins in quantity from this so-called complex in 5 per cent sodium chloride, but that it could be resolved in larger amounts in the presence of phosphate buffer (pH 7.6), barbiturate buffer (pH 9.0) or glycine buffer (pH 10.4). We have discovered that yolk *X₂* lipoglycoprotein splits into smaller molecules when placed in an alkaline medium and that *X₁* phosphoprotein tends to conjugate (thus sedimenting faster) in the same medium. Thus, the γ -livetins that Joubert and Cook observed was probably the alkaline breakdown product of *X₂* which, according to our experience, shows a somewhat similar sedimentation-rate (approximately *S* 4-5) to that of *X₁* in 10 per cent sodium chloride.

In work carried out at about the same time⁵, we had examined the ultracentrifuge patterns of egg yolk proteins in 10 per cent sodium chloride solutions and were not able to resolve as much of the so-called γ -livetins as Joubert and Cook did in their buffered experiments. Furthermore, because of previous experience with yolk proteins of the frog¹, in which case we had isolated the trailing component by ultracentrifugation and characterized it, we had suspected that the so-called γ -livetins was actually the natural form of the phosphoprotein from which phosvitin is derived. Subsequent centrifugal isolation of this fraction in the partition cell for the preparatory ultracentrifuge and chemical characterization revealed it to be nearly pure phosphoprotein (*X₁*), containing approximately 10 per cent phosphorus¹ and 50 per cent serine (unpublished work), of which almost 50 per cent was phosphoserine. (Our best sample of phosvitin prepared by the method of Joubert and Cook⁴ gave this same amino-acid analysis.) Furthermore, protein, calcium, phosphorus and lipid analysis of the remaining *X₁* plus *X₂* lipoglycoprotein fraction (see Fig. 3) revealed that no significant amount of phosphoprotein was actually complexed with the *X₂* lipoglycoprotein (lipovitellin) in 10 per cent sodium chloride, nor could there have been any large amount of 'heavy *X₁*' present, having the same sedimentation-rate as *X₂*. (We use the term 'heavy *X₁*' to describe an, as yet, theoretical molecule having twice the molecular

Fig. 3. Layering of proteins in partition cell for the ultracentrifuge

weight of X_1 , as we have described it and consisting, in theory, of two units of the X_1 having the sedimentation constant S 4.75. Turtle egg yolk X_1 -phosphoprotein appears to have approximately twice the molecular weight of hen egg yolk X_1 , but its structure has not yet been determined.)

A complex of X_1 with X_2 would have increased detectably the sedimentation-rate of the X_2 . The possibility of a third, fourth or n th component present as an impurity in the X_1 peak cannot be excluded, but X_1 does not seem to be one of these, and γ -livetins, if present, cannot be complexed with X_1 , since it would, in such an orientation, again completely modify the sedimentation-rate of X_1 .

Thirdly, from the foregoing, it is obvious that at least phosvitin as obtained by the chemical procedures of Joubert and Cook⁵, or by the electrophoretic separations of McCully, Maw and Common¹⁰, is a derived protein of a form considerably different from its physiological counterpart. In its natural state, phosvitin contains approximately 7 per cent calcium, as determined by calcium analysis of phosphoprotein (X_1) isolated ultracentrifugally from either serum or egg yolk. During the chemical or electrophoretic isolation of phosvitin, nearly all the calcium is removed. (75 per cent of the calcium associated with the phosphoprotein is irretrievably lost by a single precipitation in distilled water) and often a considerable amount of the phosphorus is removed by hydrolysis. These losses, together with a possible breaking of the phosphoprotein backbone, are reflected by a much slower sedimentation constant for egg yolk phosvitin (S 3.0) as compared with egg yolk X_1 , its naturally occurring counterpart (S 4.75) and a much faster rate of migration on paper at a pH of 8.6 (ref. 10).

Lipovitellin, as prepared by Joubert and Cook⁵, sediments at nearly the same rate as the naturally occurring egg yolk dense lipoprotein (X_2 isolated by ultracentrifugation); but in the chemically prepared form it is usually contaminated with both lipovitellin and livetins. Pre-isolation of the egg yolk granules was found by us to eliminate the livetins, since these are found only in the yolk fluid. The egg yolk granules contain only phosphoprotein and dense and light lipoproteins in significant proportion, and the light lipoproteins can be floated off by ultracentrifugation. The dense lipoprotein (lipovitellin) contains a considerable amount of polysaccharide, and approximately 20 per cent of its weight is due to the presence of lipid, mainly phospholipid². Many workers tend to obtain higher lipid values for this component, due to contamination with lipovitellin (or light lipoproteins), which are co-precipitated with the phosphoprotein and lipovitellin on dilution with distilled water.

Finally, it should be emphasized that the natural form of phosphoprotein from egg yolk (X_1) is only

half the size of its serum precursor as measured under our conditions, although it contains the same proportions of phosphorus and calcium², and the natural form of the dense lipoprotein of egg yolk (X_2) is only half the size of its serum precursor, although it contains the same proportions of total lipid and phospholipid². Thus, striking alterations have taken place in the molecules during the transfer from blood to yolk granule or from yolk granule to solution. In confirmation of these changes, when aliquots of egg yolk X_1 and X_2 and serum X_1 and X_2 were mixed and centrifuged together, the ultracentrifuge pattern shown in Fig. 4 was obtained.

Fig. 4. Sedimentation pattern of a mixture of egg granules, proteins and serum from an oestrogenized rooster

It is mainly because we do not yet know the exact nature of these and possibly other alterations that we prefer to use the terms serum X_1 and X_2 and egg yolk X_1 and X_2 . These terms both link and distinguish the four different components which may, or may not, be relatively homogeneous materials. The terms phosvitin and lipovitellin, however, refer to proteins which are known to be altered and mixed, and thus do not show due respect for the integrity of these important physiological entities.

These investigations were partly supported by contract AT-04-1-GEN-12 between the Atomic Energy Commission and the University of California, Los Angeles; aided, in part, by grants from the Eastern Seal Foundation, Society for Crippled Children and Adults; Ayerst Research Laboratories, Inc.; Squibb Institute for Medical Research; the Josiah Macy, Jr., Foundation; and U.S. Public Health Service Grant-in-Aid No. A-3793 (RI).

THE communication by Miss C.-C. Mok and me in *Nature*¹ stated our belief that we had identified phosvitin in hen's serum for the first time. Dr. Schjeide and Dr. Urist suggest that their extensive researches on the proteins of avian yolk and serum were unknown to us. In point of fact, their observations, as reported in certain of their papers^{2,3}, had encouraged us to persevere in attempts to isolate phosvitin from hen's serum by chemical procedures. Our communication, like our work, deals with a relatively very limited part of the wide range covered by the researches of Dr. Schjeide and Dr. Urist, but we regret the omission of any reference to their

researches, the more so as a full publication of our own restricted study has been delayed.

In one of their papers⁴, published prior to our communication, Dr. Schjeide and Dr. Urist point out that their serum X_1 -phosphoprotein and their egg yolk X_1 -phosphoprotein, which are ultracentrifugal entities, have a common origin and that both are phosphoproteins of high serine content but differing in sedimentation behaviour. They also point out that consideration of these results, in conjunction with those of other workers, led them to the conclusion that the phosvitin of Meecham and Olcott⁵ is a relatively pure X_1 -phosphoprotein. The different ultracentrifugal behaviour of serum X_1 -phosphoprotein and yolk X_1 -phosphoprotein, however, could indicate that the 'phosvitins' from them might differ in such properties as contents of nitrogen, phosphorus and serine. This could scarcely be established except by preparation and analysis of these phosvitins. Our reported results showed that phosvitin prepared from hen's serum by the method of Joubert and Cook⁶ had the same contents of nitrogen and phosphorus, and showed similar behaviour on zone electrophoresis on paper as did phosvitin prepared from egg yolk by the same method. This, of course, does not mean that the serum X_1 -phosphoprotein and yolk X_1 -phosphoprotein of Dr. Schjeide and Dr. Urist are the same protein, but it does suggest that these two ultracentrifugal entities would yield similar, if not identical, phosvitins when subjected to the isolation procedure of Joubert and Cook⁶.

The criticism in the foregoing communication that our phosvitin preparation is a derived protein, and in that sense an artefact, may very well be valid; and if so, then we would have been more correct to have said that we believed this to be the first occasion on which phosvitin had been prepared from hen's serum by a biochemical procedure rather than "as the first occasion on which phosvitin had been identified as a constituent of the hen's blood". For the same reasons, we consider that our communication would have been more correctly entitled 'Preparation of Phosvitin from the Serum of the Hen'. We also

suggested¹ that two lipoprotein zones observed on paper electropherograms of egg yolk and hen's serum might be related to a lipovitellin-phosvitin- γ -livetins complex and to lipovitellenin. In the light of later work, we now regard this suggestion as invalid, at least in so far as it relates to lipovitellenin. The resolution of lipoprotein zones on such electropherograms is greatly affected by the nature of the buffer.

Certainly ultracentrifugal studies, such as those of Dr. Schjeide and Dr. Urist, are likely to separate entities much more closely related to the physiological entities present in serum than are biochemical procedures or zone electrophoresis. Indeed, it is not at all easy to relate the results of zone electrophoretic experiments to the results of free electrophoretic studies, such as those of Clegg and his collaborators (for example, refs. 7-9). At the same time, simpler biochemical procedures and zone electrophoresis are more widely available techniques than ultracentrifugation and free electrophoresis; and to that extent it may be worth while to persist with the simpler techniques and to attempt to relate the results to those established by more elaborate and fundamental approaches, such as those of Dr. Schjeide and Dr. Urist, whose communication provides a timely synopsis.

NEW EVIDENCE FOR A RELATIONSHIP BETWEEN ION ABSORPTION AND PROTEIN TURNOVER IN PLANT CELLS

By DR. J. F. SUTCLIFFE

Department of Botany, King's College, University of London

SALT absorption in plants is clearly an energy-requiring process; but the mechanism by which it is achieved remains obscure¹. Experiments with metabolic inhibitors such as cyanide, azide, and carbon monoxide have confirmed the dependence on respiration, and indicate the involvement of the cytochrome oxidase system. The effects of 'uncoupling agents' (for example, 2,4-dinitrophenol) on respiration and absorption strongly suggest that ion transport is more closely linked to the supply of high-energy phosphate compounds than to electron transport, but the evidence is not unequivocal^{2,3}. Other methods of separating ion absorption from respiration must be exploited if their interrelationships are to be fully elucidated.

Steward and Preston⁴ were impressed by the closely similar influence of various external factors on salt accumulation and protein synthesis in potato tuber slices, and a scheme has been proposed whereby the two processes may be linked⁵. Other investigators⁶⁻⁸ pointed out, however, that active absorption can occur in excised roots and storage tissue cells in the absence of net protein synthesis (compare ion movements in erythrocytes, nerve and muscle cells of animals); and such claims led to the generally accepted view that the correlation sometimes observed is only an indication of a common dependence on respiration. Nevertheless, it remains possible that ion transport is linked to protein turnover (that is, breakdown and re-synthesis) which is a characteristic feature of cyto-

Fig. 1. Effect of chloramphenicol on: A, sodium absorption; B, sodium and chloride absorption; C, potassium leakage; D, oxygen absorption, by washed red beet slices. A, Sodium uptake from (a) 0.01 *M* sodium chloride (x); (b) 0.01 *M* sodium chloride + chloramphenicol (2 gm. per litre) (Δ); (c) 0.01 *M* sodium chloride + chloramphenicol (1 gm. per litre) (□), (d) 0.01 *M* sodium chloride + chloramphenicol (2 gm. per litre) (○). (—) 25° C, (---) 2° C. B, Sodium (—) and chloride (---) uptake from 0.01 *M* sodium chloride (x) and 0.01 *M* sodium chloride + chloramphenicol (2 gm. per litre) (○) at 25° C. After 48 hr., disks were transferred into the alternative medium. C, Potassium released from disks placed in 0.01 *M* sodium chloride (x) and 0.01 *M* sodium chloride + chloramphenicol (2 gm. per litre) (○) at 25° C. D, Oxygen absorbed by disks placed in 0.01 *M* sodium chloride (x) and 0.01 *M* sodium chloride + chloramphenicol (2 gm. per litre) (○) at 25° C.

plasmic proteins, even under conditions which do not favour net synthesis. This possibility may be investigated experimentally using antibiotics which are known to be specific inhibitors of protein metabolism, at least in bacteria^{9,10}.

The effect of bactericides on uptake of salt does not seem to have been investigated hitherto with higher plants, although absorption of some of these substances has been studied¹¹. Dumont¹² showed that active transport of sodium ions out of the gills of a crab, *Eriocheir sinensis*, is strongly inhibited by some antibiotics, and unaffected by others.

In the present investigation the effects of chloramphenicol on ion absorption and respiration in red beetroot and carrot root slices have been examined. The first experiment with washed beet slices showed that the antibiotic at a concentration of 1 and 2 gm. per litre (about 0.003 and 0.0006 *M* respectively) causes nearly complete inhibition of sodium absorption within about 8 hr., while at a concentration of 0.2 gm. per litre it is almost without effect (Fig. 1A). That the initial physical phase of cation absorption is largely unaffected by chloramphenicol was shown by the absence of an inhibitory effect during the first 2 hr. when an experiment was performed at low temperature. Likewise, the equilibration phase of rapid metabolic absorption

observed with washed slices, which is completed in about 8 hr., seems to be insensitive to the inhibitor, but the prolonged slower phase of active accumulation is strongly inhibited (Fig. 1B). A comparable effect on chloride, as on sodium absorption, was observed. The difference between the course of absorption of the two ions is attributable to a smaller initial physical component in the case of anion than cation uptake. The concomitant slow leakage of potassium ions from cells during absorption of sodium and chloride is enhanced by chloramphenicol in the early stages of an experiment, but is reduced later (Fig. 1C).

The effect of chloramphenicol on sodium and chloride absorption by storage tissues is completely reversible. When red beet disks which had been kept for 48 hr. in an aerated sodium chloride solution containing chloramphenicol were washed and transferred to a solution of salt alone they began to absorb immediately, at a rate comparable to that of the control tissue (Fig. 1B). Conversely, absorption of salt by tissue which had been absorbing sodium and chloride for 48 hr. was almost immediately in-

hibited on transference to a salt solution containing chloramphenicol.

A similar experiment has been performed with washed slices of carrot tissue, and the inhibition reversed 3 times (Fig. 2A). A somewhat higher concentration (4 gm. per litre) is required to produce

Fig. 2. Effect of chloramphenicol on: A, potassium absorption; B and C, oxygen absorption by washed carrot slices at 25° C. A, Uptake from (a) 0.01 *M* potassium chloride and (b) 0.01 *M* potassium chloride + chloramphenicol (4 gm. per litre) (○---○) and 0.01 *M* potassium chloride (○—○) supplied alternately. B, Oxygen absorption by disks placed in (a) 0.01 *M* potassium chloride (x); (b) 0.01 *M* potassium chloride + chloramphenicol (2 gm. per litre) (Δ); and (c) 0.01 *M* potassium chloride + chloramphenicol (4 gm. per litre) (○). C, Oxygen absorption by disks placed in (a) distilled water (x); (b) chloramphenicol (2 gm. per litre) (Δ) and (c) chloramphenicol (4 gm. per litre) (○).

Fig. 3. Effect of chloramphenicol (2 gm. per litre) on A, the development of ion absorptive capacity; B, the enhancement of respiration, caused by washing red beet tissue at 25° C. in aerated solutions. The freshly cut tissue was washed for 8 hr. in running tap water, and afterwards for 12 hr. in distilled water, before the commencement of the experiment.

A, Uptake of potassium by disks placed in (a) 0.01 M potassium chloride immediately (x---x); (b) distilled water for 2 days, and then transferred to 0.01 M potassium chloride (x---x); (c) 0.01 M potassium chloride + chloramphenicol (2 gm. per litre) immediately (O---O) and (d) chloramphenicol (2 gm. per litre) for 2 days, and then transferred to 0.01 M potassium chloride (O---O).
B, Oxygen absorption by disks placed in 0.01 M potassium chloride at 25° C. after (a) washing for 48 hr. in aerated distilled water at 25° C. (x---x); and (b) washing for 48 hr. at 25° C. in aerated distilled water containing chloramphenicol at a concentration of 2 gm. per litre (x---x).

complete inhibition of absorption in carrot than in red beet tissue.

The effects of chloramphenicol on salt absorption are manifested without any apparent influence on the rate of oxygen absorption in red beet tissue (Fig. 1D), and only a relatively small effect was observed in carrot (Fig. 2B). Calo and Varner¹³ similarly noted the insensitivity of respiration, in both freshly cut and washed potato tuber slices, to inhibition by the antibiotic. In carrot, oxygen absorption is stimulated somewhat by chloramphenicol in the absence of salt (Fig. 2C). This is possibly attributable to release of salt from the vacuoles with a result that ions gain access to the respiratory sites in the cytoplasm. The presence of salt in the external medium after the experiment supports this contention.

The observations indicate that inhibition of ion transport induced by chloramphenicol is independent of an effect on respiration. Thus, it seems unlikely that absorption is directly related to electron transport as in the mechanisms suggested by Lundegårdh² and Conway¹⁴. Furthermore, chloramphenicol at the concentration used does not influence protoplasmic streaming in either red beet or in *Elodea* leaf cells (unpublished data), which proves that energy continues to be available at least for some endergonic processes in presence of the antibiotic. Protoplasmic streaming probably depends on a rhythmic folding and unfolding of protein molecules, and it is therefore unlikely that chloramphenicol would inhibit ion absorption if uptake occurred by a mechanism dependent solely on this phenomenon, such as that suggested by Goldacre and Lorch¹⁵.

If it is assumed that chloramphenicol prevents salt absorption by inhibiting the same reaction as that affected in blocking protein metabolism, then a close relationship between the two processes is indicated. Supporting evidence for this conclusion is supplied by the inhibitory effects of nucleic acid antagonists, ribonuclease, and ultra-violet light on both ion absorption^{16,17} and on protein synthesis^{9,10}. It must be noted, however, that the concentration of chloramphenicol necessary to inhibit ion transport in carrot root slices is at least 10 times greater than that required to prevent growth of carrot callus tissue cultures under the influence of coconut milk (unpublished work). The reason for this discrepancy is

still obscure; but differences in the rate of penetration of the antibiotic into the two kinds of tissue may be responsible.

The manner in which ion transport could be linked to protein turnover or synthesis remains to be considered. It must first be emphasized that turnover probably does not involve breakdown of a complete protein molecule followed by immediate re-synthesis, but rather the continuous removal and replacement of individual amino-acids in the polypeptide chain¹⁸. A similar series of reactions to those involved in the exchange process is probably concerned also in synthesis of new protein, and, in fact, in *in vitro* experiments on incorporation of labelled amino-acids it is difficult to distinguish between exchange and net synthesis. No attempt to do this is

made in the discussion which follows. Both processes involve temporary attachment of the protein molecule, or a part of it, to a ribonucleic acid template, and it seems likely that the formation of such a protein-nucleic acid complex diminishes the capacity of the protein to bind ions both by removing available electrostatic binding sites and by reducing its chelating power, thus causing ions to be released. When the turnover site leaves the template and returns to its natural shape, binding capacity is perhaps restored and ions are taken up again. Although probable, this idea is hypothetical since no direct evidence for the reversible release of ions from protein is yet available. The ability of proteins to bind ions with a specificity comparable to that exhibited by ion transport mechanisms is well illustrated by the association of enzymes with specific activating ions.

In order that a molecule may function as an ion carrier it must not only possess the ability to bind ions reversibly, but it must also be suitably located in a membrane. The association of proteins with both surface and internal cytoplasmic membranes is quite certain, but the manner in which they are arranged in relation to the lipid and phospholipid components remains uncertain. It is likely that the membranes are in a state of continuous flux, and as a result of such movements a particular region of a protein molecule may occasionally face towards one surface of a membrane, and then the other, especially when the membrane is thin. Thus, ions which are picked up at a surface in contact with the medium may be released again on the inside where the amino-acid exchange mechanism is located. The proximity of the ribonucleic acid template may prevent the carrier site from binding ions on the inner surface immediately after exchange has occurred, and allow it to traverse the membrane unloaded before accepting ions again from the medium. The characteristic location of microsomes, which are known to be particularly active in facilitating protein turnover and synthesis, on one side of the membranes of the endoplasmic reticulum¹⁹ may be of significance in determining the direction of ion transport across cytoplasm. However, no such arrangement occurs at the vacuolar boundary of a plant cell, and yet ions accumulate in the central vacuole. Moreover, the probable thickness of the tonoplast is such that the mere turn-about of indivi-

dual protein-binding sites is unlikely to facilitate transport across the membrane as a whole. Either the ions are handed from site to site in moving from the outer to the inner surface, or other substances, for example, phospholipids, collaborate in a manner which is yet obscure. Possibly, ions are accumulated first in some of the smaller vacuoles and vesicles with which the cytoplasm abounds, and are then transferred to the central vacuole as a result of coalescence between it and the smaller ones. Vacuole coalescence is a feature of vacuome development in meristematic cells, and may well persist even in mature parenchyma.

Possibly only a few types of proteins are suitably adapted to carry out ion transport in the manner proposed. It has been suggested^{20,21} that specific proteins with enzyme-like properties (permeases and translocases) are concerned in the transfer of sugars and phosphate across bacterial membranes. Chloramphenicol may be a specific inhibitor of such carriers functioning in the plant cell, and this possibility needs to be investigated further. It is interesting to speculate that, alternatively, the capacity to bind ions reversibly may be an inherent property of all labile protein molecules, and those which are located in membranes can function as carriers in active transport. All membranous organelles may thus be capable of ion accumulation, such as has been shown in the case of mitochondria^{22,23}. Inhibition by chloramphenicol is then attributable to a general effect on protein turnover.

A feature of cells of storage tissues is that when first cut from the dormant organ they are incapable of accumulating salt, but a capacity to do so develops if they are washed for a time in an aerated solution of salt or in aerated distilled water. The development of absorptive ability has been attributed to synthesis or activation of carrier molecules resulting from enhanced metabolism induced by this treatment⁸. An experiment in which disks of red beet were washed either in a salt solution or in distilled water, in the presence and absence of chloramphenicol, has shown that the antibiotic prevents the development of absorptive capacity. Disks washed for 2 days in chloramphenicol (2 gm. per litre) at 25° C., and then

transferred to salt, absorbed potassium over the next 3 days at an increasing rate comparable to that of disks placed in salt solution at the start (Fig. 3A). Disks washed for 2 days in chloramphenicol and transferred to salt also showed a lower rate of respiration than disks washed for the same time in distilled water before transference (Fig. 3B). A similar observation was made by Calo and Varner¹³ with potato tuber tissue. The antibiotic evidently inhibits some metabolic activity upon which stimulation of both respiration and ion accumulation capacity depend.

My thanks are due to Miss E. R. Counter and Mr. A. G. Smithers for assistance in carrying out the experiments described. I am grateful to Dr. R. M. Klein of the New York Botanical Garden, who suggested to me that a study of the effect of a specific inhibitor of protein synthesis on ion absorption might prove interesting; and to Dr. J. Chayen of the Pathology Department, Royal College of Surgeons of England, for an exciting discussion of the implication of the results obtained.

PHOSPHOLIPIDS CONTAINING PHOSPHATE TRIESTER GROUPS

By DR. F. D. COLLINS

Department of Biochemistry, University of Melbourne

THE study of phospholipids has undergone rapid development in recent years not only in respect of the number of papers published annually but also because findings in the fields of respiratory enzymes^{1,2}, blood coagulation³, cell structure⁴ and transport across cell membranes^{1,3} emphasize the importance of phospholipids. Much of this activity has been stimulated by the introduction of new analytical procedures which have greatly simplified the techniques used in this field. Dawson⁴ showed that mild alkaline hydrolysis (0.2 N sodium hydroxide at 37° for 20 min.) of phospholipids yielded a mixture of glyceryl phosphoryl choline, glyceryl phosphoryl ethanolamine, glyceryl phosphoryl serine, glyceryl

phosphoryl glycerol, glyceryl phosphoryl inositol and glycerol-1-phosphoric acid which could be separated by paper chromatography. It was assumed that each water-soluble phosphate ester was derived from one phospholipid and hence the specific radioactivity of each phospholipid, if labelled with phosphorus-32, could be deduced from that of the corresponding water-soluble phosphate ester. Chromatography on silicic acid was shown by Lea, Rhodes and Stoll⁵ to effect a separation of phospholipids into well-defined components, and Marinetti, Erbland and Stotz⁶ obtained good separations using chromatography on silica-impregnated paper and di-*n*-butylketone/acetic acid/water (40:25:5 by volume).

* Phosphatidyl inositol, sphingomyelin and phosphatidic acid-like materials.

It was surprising to find that the analytical methods⁷ introduced in this laboratory gave results that were at variance with those obtained by the procedures referred to above. In this laboratory the phospholipids are dinitrophenylated using 1-fluoro-2:4-dinitrophenyl-benzene followed by methylation using diazomethane, and the resulting phospholipid derivatives are separated, by low-temperature chromatography on cellulose at -20° using acetone, into fractions soluble and insoluble respectively in acetone, and then each fraction is further resolved by counter-current distribution. Table 1 shows a comparison with the results obtained by Hanahan, Dittmer and Warashina⁸, who used silicic acid chromatography. The major difference is in the 'complex' phospholipids which constitute 39 per cent of the total rat-liver lipids and in which the molecular weight is at least double that of the known phospholipids. This fraction has not been detected by other workers.

There are two possible explanations for this discrepancy: one is that the 'complex' phospholipids are degraded by the silicic acid chromatography, and the other is that the chemical treatment (dinitrophenylation and methylation) used in this laboratory⁷ results in the production of artefacts not existing in the original phospholipid mixture.

To test these alternatives, rat liver lipids were treated with silicic acid (Mallinckrodt), the lipids recovered quantitatively, dinitrophenylated and methylated and separated by counter-current distribution into two fractions: *A*, that containing phosphatidyl ethanolamine and phosphatidyl serine; *B*, that containing the 'complex' phospholipids. The amounts of these compounds were determined from the content of dinitrophenyl-groups and the results are shown in Table 2. Not only was the proportion in fraction *B* of the 'complex' phospholipids decreased,

Table 2. EFFECT OF SILICIC ACID ON PHOSPHOLIPIDS

Phospholipids from the same sample of rat liver lipids were treated with silicic acid as shown below, the lipids were then completely eluted and treated as described by Collins and Wheeldon (ref. 7).

All results are expressed as gm. atoms of phosphorus per 100 gm. atoms of total lipid phosphorus.

Fraction	<i>A</i> Phosphatidyl ethanolamine and serine	<i>B</i> 'Complex' phospholipids
Treatment		
Control	15	32
Lipids (800 mgm.) stood with 12 gm. silicic acid in chloro- form-methanol (1:1 by vol.) for 48 hr.	15	20
Lipids (800 mgm.) chromato- graphed on silicic acid (12 gm.)-'Celite' (8 gm.) Rate of flow 3-4 ml/min Solvents, chloroform-meth- anol in the proportions used by Hanahan <i>et al.</i> (ref. 8)	11	18

but also further examination revealed considerable qualitative changes both in respect of their behaviour on counter-current distribution and in their solubility in acetone and in water. The dinitrophenylated and methylated 'complex' phospholipids are insoluble in water and very soluble in acetone but, after treatment with silicic acid, only 6-10 per cent of the total phospholipids had these properties. Of the remaining dinitrophenyl-containing materials in fraction *B*, 4 per cent (of the total phospholipids) were insoluble in acetone and 3 per cent were soluble in water. The small amount of 'complex' phospholipid which appeared to be unchanged had the molar ratio dinitrophenyl-groups/phosphorus = 0.5 but, unlike the original material, choline was not detected. The fall in the amount of 'complex' fraction was not accompanied by a corresponding rise in the phosphatidyl ethanolamine and serine, and thus there was a disappearance of about a third of the total amino-nitrogen (ethanolamine and serine). These results show that silicic acid can degrade phospholipids and that its effect is on the 'complex' fraction. Other workers⁶ did not consider the possible presence of unidentified lipids which might be sensitive to silicic acid, but were content to show that silicic acid chromatography was without effect on lecithin and phosphatidyl ethanolamine.

While the above evidence demonstrates that silicic acid can degrade some phospholipids, this of itself does not dispose of the possibility that the process of dinitrophenylation and methylation may result in artefacts. Reasons for believing otherwise are discussed in previous papers⁷, and are augmented by the following experiment (Table 3) in which the object was to show that the specific radioactivity of the phosphorus, esterified to ethanolamine, in phosphatidyl ethanolamine is greater than that in the complex phospholipids. As the methods available did not separate the serine component, the specific radioactivity of the ethanolamine component was estimated from the specific radioactivity of the combined fraction on the assumption that the radioactivity of the serine component was zero. Although this is not the case^{10,11}, it is the least favourable assumption that can be made in that it minimizes the differences between the two ethanolamine-containing materials. The phosphatidyl ethanolamine and serine (as the dinitrophenylated and methylated derivatives) were isolated by counter-current distribution and re-distributed in heptanemethanol for 120 transfers. A single dinitrophenyl-containing peak was obtained with a partition coefficient of 0.50, in which the molar ratio of dinitrophenyl-groups/phosphorus was 1.0 and which contained 86 per cent phosphatidyl ethanolamine and 14 per cent phosphatidyl serine. The specific radioactivity of this material is shown in Table 3. Because the 'complex' phospholipids contain approximately two atoms of phosphorus to each molecule of ethanolamine or serine, it was necessary to effect a partial hydrolysis before the radioactivity could be related to the amino-compounds. The complex fraction was treated with 0.2 *N* sodium hydroxide in 50 per cent aqueous methanol for 20 min. at 37° , the mixture neutralized with 'Zeokarb-225' (H-form), and the fatty acids removed by extraction with diethyl ether. Paper chromatography in phenol-water of the water-soluble materials showed the presence of two phosphate-containing¹² spots (R_F 0.73 and 0.54). Both spots gave a positive reaction for a *cis*-glycol group¹³; the slower spot has not yet been identified, but the faster-moving material was yellow, indicating

Table 3. INCORPORATION OF RADIOPHOSPHORUS INTO PHOSPHATIDYL ETHANOLAMINE AND THE ETHANOLAMINE-CONTAINING PORTION OF THE 'COMPLEX' PHOSPHOLIPIDS

A rat was intravenously injected with 0.8 mc. of sodium dihydrogen phosphate- ^{32}P (0.01M, pH 7.0) in 0.1M sodium citrate (pH 7.0), killed 90 min. later, the liver lipids extracted, and processed as described by Collins and Wheeldon (ref. 7) and Shotlander and Collins (ref. 9).

	Specific radio-activity (counts/min./ $\mu\text{mole P}$)	Ratio serine-nitrogen to total amino-nitrogen	Specific radio-activity of ethanolamine moiety, assuming that of serine is zero (counts/min./ $\mu\text{mole P}$)
Phosphatidyl ethanolamine and serine	13,700	0.14	15,900
'Complex' phospholipids (phosphorus esterified directly with ethanolamine and serine)	9,100	0.24	12,000

the presence of a dinitrophenyl group. The yellow spot was eluted with water, and analysis indicated that the molar ratio of dinitrophenyl-groups/phosphorus was 1.0, and it was concluded that this was glyceryl phosphoryl N-2:4-dinitrophenyl ethanolamine (or serine, as no separation was obtained in this solvent system). The specific radioactivity and serine content of this material are shown in Table 3. It will be seen that the specific radioactivity of the phosphatidyl ethanolamine is between 1.50 and 1.32 times that of the phosphate ester containing ethanolamine, which was derived from the complex fraction and, as the combined counting and chemical errors do not exceed 4 per cent, this difference is highly significant.

These results show that the dinitrophenylated and methylated 'complex' phospholipids represent a distinct and real fraction, but beyond indicating that they are sensitive to silicic acid, they provide no information as to their structure. Previous work⁷ has shown that the molar ratio of dinitrophenyl-groups/phosphorus is usually 0.5 but may be 0.67. Qualitative analysis^{7,9} has also shown that choline is present in some but not all the components that make up the 'complex' phospholipid fraction and that inositol is absent. Further information was obtained in experiments in which the dinitrophenylated and methylated 'complex' phospholipid fraction (50 mgm.) was treated with one of the following reagents: triethylamine (0.1 ml. in 10 ml. of diethyl ether saturated with water and left 12 hr. at 20°), tetramethyl ammonium hydroxide (0.1 ml. of a 25 per cent (w/v) aqueous solution added to 10 ml. of diethyl ether saturated with water and left 12 hr. at 20°), acetic acid (8 ml. of glacial acetic acid and 2 ml. water and left 30 min. at 40°). In addition, chromatography on 'Hyflo-Supercel' or on silicic acid (Lights or Mallinckrodt) gave similar results. The total lipids were recovered after treatment, treated with diazomethane and submitted to counter-current distribution. One of the products isolated had a molar ratio of dinitrophenyl-groups/phosphorus of 1.0 and was indistinguishable from the methyl ester of dinitrophenyl phosphatidyl ethanolamine and serine. This methyl ester was not obtained if the preliminary 'hydrolytic' treatment was omitted, and hence one must conclude that the preliminary treatment gave rise to dinitrophenyl phosphatidyl ethanolamine or serine. The only groups present in these compounds which are available for chemical bonding are the free hydroxy group on the phosphorus

and the carboxy group on the serine, and it thus follows that the 'complex' phospholipids contain either a phosphate triester or a serine-carboxylic ester. This last alternative is unlikely, not only because it could account for only 24 per cent of the 'complex' phospholipids but also because carboxylic esters such as the glycerides appear to be quite stable to silicic acid chromatography. Thus, one must infer that the 'complex' phospholipids are distinguished from the remaining phospholipids, which are phosphate diesters, by the presence of a tertiary ester of phosphoric acid. The nature of the compound to which the phosphatidyl ethanolamine is esterified has not been fully elucidated, but it is clear that it must contain phosphorus and is in all probability another phospholipid.

Two types of compounds are possible: (1) those in which phosphatidyl ethanolamine is esterified with the free hydroxy group in such a compound as lysolecithin, sphingomyelin or cardiolipin; (2) the second type can be imagined in which phosphatidyl ethanolamine is linked by glycerol (or similar compound) to another phospholipid and the resulting compound would have two phosphate triester groups. The suggested structures are shown below: the first type would be a phosphatidyl ethanolamine-lysolecithin, (I), whereas the second would be, for example, 1-(phosphatidyl ethanolamine) 3-(phosphatidyl choline) glycerol (II). Complete or partial hydrolysis of compounds such as those suggested above would yield products which would be identical with those which are in fact obtained, and this helps to explain their non-recognition in the past. Further, the splitting of the phosphate triester on silicic acid would either yield the classical forms (phosphatidyl choline, ethanolamine or serine) or such compounds as lysolecithin or lysophosphatidyl ethanolamine.

The occurrence of lysolecithin in animal tissues has only been reported in recent years, and it is interesting to note that in every case it was isolated either by silicic acid chromatography⁸, or by chromatography on paper impregnated with silicic acid using aqueous acetic acid in the solvent system⁶, or by counter-current distribution using aqueous acetic acid as a component of the solvent mixture¹⁴. Both silicic acid and acetic acid have been shown here to be effective

in degrading the 'complex' phospholipid fraction, and lysolecithin has not been detected by the methods in use in this laboratory. The 'complex' or triester fraction has been shown to be present in rat tissues (liver, kidney, heart, lung, brain, spleen and intestine), sheep brain, human blood plasma, influenza virus, yeast and cabbage leaf, and the amounts have varied from 15 per cent for human blood plasma to 60 per cent for sheep brain.

The fact that phospholipids consist of about 60 per cent in the form of phosphate diesters and 40 per cent as triesters means that most investigations on phospholipids have neglected the study of a major portion. The procedure described by Dawson⁴ involving alkaline hydrolysis, which has been widely used for the study of the exchange of inorganic phosphorus-32 with phospholipids, cannot distinguish between the diesters and the triesters, as the triesters of phosphoric acid are labile to alkali and a diester would be formed.

The procedure⁷ developed in this laboratory suffers from the disadvantage that derivatives of the phospholipids are isolated and not the native materials. In certain fields such as in the study of blood coagulation, this is a serious drawback as the object is the isolation of material with biological activity. Apart from the fact that the native 'triester' phospholipids are more soluble in ethanol than phosphatidyl ethanolamine or serine⁷, no work has been attempted on their isolation in an unaltered condition. An analytical method⁷ exists for the determination of this group of phospholipids and hence attempts at their isolation

can be readily followed. However, the solution to the problem of obtaining the native materials may be as readily solved by chemical synthesis, and in the meanwhile, much work remains to be done on the elucidation of the structures of the phosphate triester phospholipids.

ACTION OF SPERMINE ON SOLUBLE RIBONUCLEIC ACID AND SOME POLYNUCLEOTIDES

Spermine Fractionation of Soluble Ribonucleic Acid of Rabbit Liver

THE unique biological role of cytoplasmic, or soluble, ribonucleic acid, as an acceptor for acyl-activated amino-acids, and as a donor of the amino-acyl moiety to microsomal protein, has been established¹⁻³. Furthermore, it has been found that in any one soluble ribonucleic acid preparation there are a finite number of acceptor sites, presumably one for each polynucleotide chain, and it has been shown by several investigators^{2,4,5} that each amino-acid is bound to soluble ribonucleic acid in a fixed amount and independently from other amino-acids. From these observations it has been inferred that there is a specific soluble ribonucleic acid chain for each amino-acid, and indeed it has been possible to separate, at least partially, different species of soluble ribonucleic acid by various experimental procedures. These procedures⁶⁻⁸ may be based on either (a) special properties conferred by the presence of an amino-acid at the nucleoside end, or (b) differences in the physicochemical properties of the various chains. Thus Brown *et al.*⁶ were able to prepare in essentially pure form the soluble ribonucleic acid species specific for tyrosine or histidine by taking advantage of the ability of soluble ribonucleic acid labelled with these amino-acids to form diazonium compounds with a polyaminoazostyrene resin at neutral pH. On the other hand, partial separation of amino-acid specific

soluble ribonucleic acids based on physicochemical properties of the amino-acid-free soluble ribonucleic acid were obtained by Smith *et al.*⁷ by column chromatography and by Bowman⁸ by electrophoresis on starch. More promising results were obtained by Holley *et al.*⁹ through application to soluble ribonucleic acid of the counter current distribution system of Warner and Vaimberg¹⁰.

Purification of soluble ribonucleic acids specific for valine or proline was achieved, as described here, by utilizing the well-known ability of polyamines to form insoluble complexes with polynucleotides¹¹. The procedure was based on the assumption that amino-acid-specific soluble ribonucleic acids differ sufficiently in their chemical composition (base composition or sequence) to allow separation. This assumption is in accord with the results of Holley *et al.*⁹ and Warner and Vaimberg¹⁰ and is supported directly by the findings of Klee and Cantoni¹² that the specificity of soluble ribonucleic acid for proline, valine or leucine is not related to molecular weight.

Rabbit liver soluble ribonucleic acid was isolated from the 'pH 5 enzyme' by a sodium chloride extraction procedure to be described in a forthcoming publication. On treatment of soluble ribonucleic acid with a two- to three-fold excess of spermine tetrahydrochloride at pH 5.6 and low ionic strength (0.02 M sodium succinate buffer in 0.03 M sodium chloride) approximately 70 per cent of the ultra-violet absorbing material is precipitated. The sper-

Table 1. SPERMINE FRACTIONATION OF SOLUBLE RIBONUCLEIC ACID

	Amino-acid acceptor units		Specific activity (μmoles of amino-acid/125 nucleotides)		P/V
	Proline	Valine	Proline	Valine	
Rabbit liver Soluble ribonucleic acid	100	100	0.115	0.041	2.8
Supernatant	24.8	89	0.092	0.091	1.0
Precipitate:					
Extract 1	10.5	10	0.194	0.066	2.9
Extract 2	26	6	0.276	0.039	7.1
Extract 3	25.7	10	0.316	0.035	9.1

The starting material, and the various fractions were tested as follows for their ability to accept activated amino-acids: the reaction mixtures (0.5 ml.) contained the following components; adenosine triphosphate, 10 mM; magnesium chloride, 20 mM; sodium chloride, 2.8 mM; potassium phosphate buffer, pH 7.6, 2.8 mM; ^{14}C amino-acid, 0.05 mM; and approximately 8 optical density units of soluble ribonucleic acid. Appropriate activating enzymes¹⁴ were added to start the reaction; incubation time, 15 min at 37°. The reaction was stopped by addition of 0.5 ml. of 6 per cent chloroform. The precipitate was washed 3 times with 8 per cent chloroform, once with ethanol, suspended in 0.75 ml. of 6 per cent chloroform, and hydrolysed for 30 min. at 100°. After neutralization with potassium hydroxide, the optical density of this solution was determined and an aliquot was plated and counted. Values are corrected for self absorption. Amino-acid acceptor units thus determined are in counts/min./o.d. at 260 mμ.

mine-soluble fraction is 2-3 times richer in valine-specific soluble ribonucleic acid than the starting material. Repeated extraction of the spermine-insoluble fraction with small volumes of phosphate buffer, 0.025 M, pH 7.2 in 0.05 M sodium chloride, yields a fraction enriched by about the same factor with respect to proline acceptor ability. Total recovery in both cases is satisfactory (Table 1). On the assumption that in a single soluble ribonucleic acid chain there is only one acceptor site for the activated amino-acid and on the basis of a chain-length of 125 nucleotides, the partially purified proline specific soluble ribonucleic acid is approximately 25-30 per cent pure, while the valine specific species is about 8-10 per cent pure. (The value of 125 for chain-length is based on a molecular weight of 45,000-55,000, as determined by sedimentation and viscosity measurements¹³.)

It is noteworthy that the pH at which the fractionation is carried out is relatively critical. Thus, essentially no fractionation was achieved at pH 6 or 4.8. At pH 5.2 the results obtained are in the same general direction but partition is less precise. Intermediate pH's have not yet been investigated. Since the ability of spermine to react stoichiometrically with soluble ribonucleic acid is not dependent on pH, these results suggest that the determining feature which permits fractionation of a population of various soluble ribonucleic acid chains relates to the pK_a of the amino group of cytosine (and/or adenosine) in the polynucleotides.

Work by Huang and Felsenfeld using synthetic polynucleotides as model systems provides support for this hypothesis. These results are detailed in the following communication. It is of interest to point out that rabbit liver soluble ribonucleic acid has a high cytosine content¹⁴, as is also the case for soluble ribonucleic acid derived from *E. coli* or yeast^{15,17}.

Solubility of Complexes of Polynucleotides with Spermine

Cantoni has shown in the preceding communication that the solubility of soluble ribonucleic acid-spermine complexes is dependent on pH. The solubility of nucleic acid complexes with poly-cations has also been the subject of investigations by Razin and Rozansky¹, who studied polyamine-nucleic acid interactions, and by Chargaff *et al.*², who used polylysine and other poly-cations to fractionate deoxyribonucleic acids. The results presented in this communication are concerned with the behaviour of complexes of spermine with synthetic polyribonucleotides.

If an equivalent of spermine per mole of polymer phosphorus is added to a distilled water solution of heat-denatured calf thymus deoxyribonucleic acid at pH 6.5, a precipitate forms at once and most of the nucleic acid may be separated by centrifugation. Similar results were obtained with the synthetic polyribonucleotides, polyadenylic acid and polyinosinic acid. The polypyrimidines, polycytidylic acid and polyuridylic acid formed somewhat more soluble complexes with spermine, though precipitation was observed in the presence of excess spermine. Under conditions similar to those of some of the experiments described here (polymer phosphate concentration about 5×10^{-5} M, buffer concentration about 0.01 M, spermine concentration about 2×10^{-4} M), addition of spermine to separate solutions of polyadenylic acid, polyinosinic acid, polycytidylic acid and polyuridylic acid resulted in immediate extreme elevation of the absorption spectrum because of scattering from aggregates. Centrifugation at 16,000 g in a Servall centrifuge for 10 min. was sufficient to remove from suspension 80 per cent or more of the polyadenylic, polyinosinic and polycytidylic acids. Only 50 per cent of the polyuridylic acid-spermine was removed, but the spectrum of the supernate showed that the remaining material was in an aggregated form. The same solubility properties were observed for all these polynucleotides at pH 6.8 (cacodylate buffer) and pH 4.1 (acetate buffer).

When polyadenylic acid ($S_{20} = 8.4$) and polyuridylic acid ($S_{20} = 5.4$) are mixed in 1:1 base ratio in the presence of 2×10^{-3} M magnesium chloride, the two-stranded poly(adenylic + uridylic) complex is formed³. (Sedimentation coefficients, given in Svedberg units, were measured in 0.05 M sodium chloride, 0.005 M cacodylate buffer, pH 6.8, using

a Spinco model *E* ultracentrifuge equipped with ultra-violet optical system. According to Fresco and Doty⁵ the value of S_{20} found for polyadenylic acid corresponds to a molecular weight of about 4×10^5 . The addition of an equivalent of spermine to this complex at pH 6.8 (or any other pH between 6.8 and 4.5) caused total precipitation. However, if polyinosinic acid ($S_{20} = 6.3$) and polycytidylic acid ($S_{20} = 5.2$) were similarly caused to combine in 1:1 ratio⁴ by adding magnesium chloride, the complex formed when spermine was added was soluble at pH 7. (All the observations concerning solubility of spermine complexes were made within 2 hr. after addition of spermine. After 24 hr. small amounts of precipitation have been observed in poly (inosinic + cytidylic)-spermine at pH 6.8.)

The solubility of the poly (inosinic + cytidylic)-spermine complex has been studied as a function of pH. To a 1-ml. sample of 5×10^{-5} M poly (inosinic + cytidylic) in 2×10^{-3} M magnesium chloride was added 0.1 ml. of 0.1 M cacodylate or acetate buffer of the appropriate pH. The absorption spectrum was determined in a Cary model 14 spectrophotometer, and 0.04 ml. of 1.25×10^{-3} M spermine tetrahydrochloride was added. The spectrum was plotted again both before and after centrifugation at 16,000 *g* in a Servall centrifuge for 15 min. At every pH between 6.8 and 5.1 there was no change in the absorption spectrum (aside from dilution effects) before centrifugation, and no more than a 5 per cent decrease in optical density after centrifugation. There was no further decrease in optical density with longer periods of centrifugation. However, when pH 4.5 buffer was used the addition of spermine resulted in immediate aggregation and increase of absorption values throughout the spectrum. Centrifugation removed these aggregates; only 70 per cent of the original polynucleotide remained in solution. When the experiment was repeated with pH 4.1 buffer only 30 per cent of the poly (inosinic + cytidylic) was still soluble after centrifugation.

This behaviour is in contrast with that of poly (adenylic + uridylic) in 2×10^{-3} M magnesium chloride. Using conditions similar to those described for poly (inosinic + cytidylic) it was found that poly (adenylic + uridylic) precipitated completely both at pH 6.8 and pH 5.1. In the experiment shown in Fig. 1 equal volumes of 5×10^{-5} M poly (adenylic + uridylic) and 5×10^{-5} M poly (inosinic + cytidylic) (both in 2×10^{-3} M magnesium chloride) were mixed and 0.1 ml. of 0.1 M cacodylate buffer (pH 6.8) added to a 1.0-ml. aliquot. The resultant spectrum (curve A) was the mean of the spectra of poly (adenylic + uridylic) and poly (inosinic + cytidylic) taken separately. Spermine (0.15 ml. of 1.25×10^{-3} M) was added directly to the cuvette. The spectrum gave evidence of aggregation and after centrifugation only the spectrum of the poly (inosinic + cytidylic) remained, as demonstrated by direct comparison with a poly (inosinic + cytidylic) control containing the same concentrations of poly (inosinic + cytidylic) and of spermine used in the solution of curve A. Spermine thus effects a complete separation of poly (inosinic + cytidylic) from poly (adenylic + uridylic) under these conditions.

It does not appear likely that the differences in solubility described here were the result of differences in molecular weight. The polyinosinic and polycytidylic acids used in these experiments were precipitable, and so was incompletely combined poly (inosinic + cytidylic), or completely combined poly-

Fig. 1. Absorption spectrum of a solution originally containing 2.8×10^{-4} M poly (adenylic + uridylic), 2.8×10^{-4} M poly (inosinic + cytidylic), and 0.001 M pH 6.8 cacodylate buffer. Total volume 1.1 ml. Curve A, before addition of spermine; Curve B, solid line, after adding 0.15 ml. of 1.25×10^{-3} M spermine and centrifuging. Dotted line, a solution containing 2.0×10^{-5} M poly (inosinic + cytidylic), 0.080 M cacodylate buffer, and 1.5×10^{-4} M spermine. In all experiments spermine was added as the tetrahydrochloride.

mer at pH 4.1. With smaller polyinosinic and polycytidylic acids (S_{20} equal to 2.6 and 2.1 respectively) the addition of polycytidylic acid-spermine solution to the polyinosinic acid-spermine precipitate caused rapid solution of the polyinosinic acid and immediate appearance of the poly (inosinic + cytidylic) spectrum. The simplest conclusion is that only the well-ordered poly (inosinic + cytidylic) structure⁴ is capable of forming soluble complexes with spermine. The precipitation of the poly (inosinic + cytidylic)-spermine complex formed at low pH may be the result of partial derangement of the poly (inosinic + cytidylic) structure as cytosine is titrated⁵ in the neighbourhood of pH 4.5. The spectral shifts that occur when the pH is lowered to 4.5 indicate that cytosine is being titrated, though this does not necessarily mean that the hydrogen bonding to inosine has been destroyed⁶. If structure is important, then it must be assumed that the poly (adenylic + uridylic) structure⁷ differs from that of poly (inosinic + cytidylic) sufficiently to affect the solubility properties.

The similarity of the behaviour of these synthetic polymers to that of soluble ribonucleic acid may be accidental, but there is little doubt that fractionation of ordered polynucleotides may be effected with spermine, and that this fractionation has a pH dependence resembling that of soluble ribonucleic acid. Further investigations with complexes of the co-polymers poly (adenylic; uridylic) and poly (inosinic; cytidylic) are in progress.

PHYSICS

Standard Unit of Pressure in Vacuum Physics

A UNIT of pressure in terms of the height of the column of a liquid manometer is essential, since such an instrument, including the compression manometer (McLeod gauge), is indispensable in the measurement of low pressures. Even in the recent methods¹ developed for measuring pump speeds and calibrating vacuum gauges, in which the only magnitude needed to be determined accurately is a rate of gas flow, manometers are required.

The use of the existing practical unit (mm. mercury) has already been challenged by the tremendous development of the physics and technology of vacuum. This unit is characterized by the following features: (1) It does not express a pressure in the basic terms of force per unit area. (2) It is not related decimally to the absolute units of pressure. (3) Its value is affected by temperature and geographical position. While the third characteristic appears to be a disadvantage which can be eliminated by the application of some corrections, the second characteristic would require fundamental alteration in the definition of the unit.

The pressure h in mm. mercury is evaluated by applying the hydrostatic equation $p = g \Delta u h$, where p is the absolute pressure in c.g.s. units and $u = 1 \text{ mm.} = 0.1 \text{ cm.}$ is the unit of the column height. Since gravity $g = 980.665 \text{ cm. s.}^{-2}$ and mercury density $\Delta = 13.5951 \text{ gm. cm.}^{-3}$ at 0°C. are considered as standard values, we obtain for $h = 1 \text{ mm. mercury}$: $1 \text{ mm. mercury} = g \Delta u = 1.333, 22 \times 10^3 \text{ dyn. cm.}^{-2}$

All previous suggestions² aimed at standardization of the pressure unit have not sought to alter this relationship in such a way that p and h would become simply related. In the following I will discuss this possibility as a practical proposition.

The main point is to transform the above relation into:

$$g \Delta u = 10^n$$

where n is an arbitrary integer. Here only u and g can vary, the latter factor being limited between 978 and 983, the gravity at the equator and pole, respectively. It results that u has two limits $u_1 = 0.07482 \times 10^{-3} \text{ cm.}$ and $u_2 = 0.07528 \times 10^{-3} \text{ cm.}$ An acceptable magnitude for practice would be $u' = 0.075 \text{ cm.} = 3/4 \text{ mm.}$ From this assumption it follows $n = 3$ and for gravity the value $g' = 10^6/75 \Delta \text{ cm. s.}^{-2}$ or $g' = 980.7455 \text{ cm. s.}^{-2}$ within one part in 10^4 .

Thus we have:

$$p = g' \Delta u' h' = 10^3 h' \text{ dyne cm.}^{-2}$$

The pressure corresponding to $h' = 1$, that is, $p = 10^3 \text{ dyne cm.}^{-2}$, may be taken as standard unit and conveniently termed 'vac'. This pressure unit, $1 \text{ vac} = 10^3 \text{ dyne cm.}^{-2}$, corresponds to a mercury column of exactly 0.75 mm. height under the conventional conditions: g' as above and $\Delta = 13.5951 \text{ gm. cm.}^{-3}$ at 0°C. Therefore, pressures expressed in vac are measured by taking 0.75 mm. instead of 1 mm.

as unit of the mercury column. Since $0.7500615 \text{ mm. mercury} = 10^3 \text{ dyne cm.}^{-2}$, 1 vac may for all practical purposes be equated to $3/4 \text{ mm. mercury}$ within less than one part in 10^4 .

Recommendation of vac as standard unit of pressure would require the adoption of the conventional value g' , which is different from the standard gravity. Such a decision will not cause any confusion because the latter value has little use in vacuum physics. However, vacuum physicists will greatly benefit by simplification of conversion to the absolute unit. No complications regarding the recalibration of vacuum gauges are involved.

Radiative Recombination in Gallium Phosphide Point-Contact Diodes

CAREFUL observation of the radiation emitted from point-contact gallium phosphide diodes under conditions of reverse bias has shown that the luminescence is associated with the recombination of carriers in the breakdown region of the current-voltage characteristic. Electroluminescent radiation has been observed in gallium phosphide by several workers¹⁻³. The electroluminescence appears to be associated with p - n junctions formed between the p -type bulk and an n -type skin on the surface of the material and at grain boundaries. From measurements of optical absorption in gallium phosphide, a value for the energy gap at room temperature of 2.19 eV. was deduced. This value is in good agreement with the value of 2.20 eV. for the room temperature band gap measured at Bell Telephone Laboratory⁴.

We obtained a measurement of the energy spectrum of the recombination radiation by a simple and convenient arrangement of a diffraction grating and a 35-mm. camera. A diffraction grating with 15,000 lines per inch was attached to the 50-mm. extension bellows of an Exakta camera, and a 100- μ slit was affixed in the focal plane of the lens. With this arrangement, both zero-order and first-order spectra are visible on a single frame. The gallium phosphide luminescence was exposed through the slit to Ansco Super Hypan film for times up to 30 min. Fig. 1 is a print of one such exposure ($\times 10$). (The zero-order spectrum is not shown.) The two discrete lines at the left of the figure are the two prominent lines from the spectrum of gallium (4033 Å. and 4172 Å.), and are used for calibrating the spectrograph. They may be obtained by producing an arc between the point contact and the gallium phosphide crystal after the exposure of the recombination radiation has been made. Fig. 2 is a densitometer trace of the negative showing the wave-lengths and energies of the observed radiation. Correcting for the spreading effect due to the width of the slit, the energy of the recombination radiation is here observed to be between 1.96 and 2.19 eV., with a peak density at 2.12 eV. The peak

Fig. 2. Densitometer trace of the first-order spectrum of recombination radiation from gallium phosphide point-contact diode

density and minimum energy values correlate with those published by Wolff *et al.*¹. However, interestingly enough, our maximum energy 2.19 eV. corresponds closely to our measured value of the minimum energy between the conduction and valence bands, and Wolff's maximum energy 2.32 eV. corresponds to his measured value of the band gap. Although the actual operating temperature of the diode was not determined, operation of the device in the breakdown of the reverse characteristic dissipated sufficient heat to increase its temperature significantly. Therefore,

deductions concerning the probability of direct interband transitions from our results are not made, pending precise temperature measurement and control of the diode under operating conditions. The point-contact gallium phosphide diodes were prepared from small single crystals of *p*-type material, grown by the vapour-phase transport of the compound. A rather wide range of peak reverse voltages was observed, varying from 10 to 60 V. The slope of the reverse characteristic of the breakdown region also varied from diode to diode, and in some cases multiple slopes were observed.

It has been shown that in some silicon junctions, avalanche breakdown is accompanied by the emission of light at isolated points which are presumably associated with regions where dislocations pass through the junction². Goetzberger and Shockley^{3,4} have recently shown that the multiple slopes seen in the breakdown region of some silicon junctions are associated with isolated areas of high density of impurity which penetrate the *p-n* junction. Such a correlation between the onset of luminescence at isolated points in the breakdown region and discontinuities in the slope of the reverse characteristic was observed in our gallium phosphide junctions. The luminescent points appeared to be on the top surface of the crystal and were generally separated from the point contact, indicating that rectification was not restricted to the point contact, but was also evidently associated with a junction between an *n*-type surface skin and the bulk *p*-type material. Fig. 3 is the drawing of an oscilloscope trace of the reverse characteristic of a point-contact gallium phosphide diode. As the voltage was increased, new points of luminescence were observed to appear at the same voltages as the discontinuities in the slope of the reverse characteristic. Appreciation is expressed to J. F. Miller for preparing the gallium phosphide and to Dr. P. W. Davis for the band-gap determination.

Determination of Fluid Saturation in Porous Media by a Radio-Frequency Method

A KNOWLEDGE of fluid saturation at any one cross-section is very often required when studying fluid behaviour in porous media. Investigators measuring this have employed a variety of techniques including resistivity methods^{1,2}, radioactive tagging of a fluid³, X-rays⁴, and light absorption⁵. Very often it is required to know the extent of saturation of water or a water solution in a porous medium. Since water has a high dielectric constant, it has seemed worth while to consider a method which is dependent on this fact, and which would be used primarily for water or water solution. The technique proposed here has its origins in high-frequency titrations^{6,7}, where a high-frequency signal is fed into an electrode or coil on the titration cell. Changes in composition during the course of a titration are then measured in terms of change in current or voltage of the plate or grid of the oscillator valve or change in frequency of the oscillator. A change in degree of saturation in a porous medium will produce a similar loading effect in an oscillator as a high-frequency titration, and consequently, a similar method of detection may be employed.

Fig. 1. Determination of fluid saturation

In the present arrangement (Fig. 1) the signal from a modified Hartley oscillator was fed into a silver paint electrode on one-half of a 'Perspex' cell (internal diameter and height 4 and 8.9 cm. respectively) and to the X-plates of an oscilloscope (Heathkit O-11). The electrode on the opposite side of the cell was earthed and the cell was screened by surrounding it with a copper shield. The signal from the crystal-controlled reference oscillator (a Heathkit TO-1 Colpitts oscillator) was sent to a 4-watt pre-amplifier (General Electric Phono-mic) and the amplified signal fed into the Y-plates of the oscilloscope. Two frequencies were used in the present work, 500 kc./sec. and 1,000 kc./sec., by selecting the appropriate crystal in the reference oscillator. It was found in the initial experiments that the oscillator was quite sensitive to temperature, and a slow frequency drift took place at room temperature. To obviate this difficulty the oscillator was enclosed in a constant-temperature cabinet.

With the cell empty, the variable oscillator was tuned to the frequency of the reference oscillator by means of a vernier on the variable capacitor of the oscillator. The point at which both signals were in phase on the oscilloscope served as an initial reference point. The cell was then packed with an unconsolidated silica sand of $-30 +40$ U.S. sieve size and the oscillator re-tuned to reference oscillator frequency.

This point served as a reference point for the subsequent measurements with a fluid in the porous medium. The extent of fluid saturation of the packed cell was measured by the change in capacitance in the Hartley circuit in terms of vernier divisions, at balance, from that for the dry medium. Removal of the cell from the oscillator signal cable for unpacking could result in a capacitance change when the cell was replaced: however, with experience it was found that the initial reference point could be attained by adjustment of the position of the cable.

A series of fluid saturations was obtained by mixing a known quantity of fluid, in this case distilled water or 0.05 N sodium chloride solution, with a known quantity of sand and packing the resultant homogeneous mixture into the cell, *in situ*. Porosity of the medium was 34.3 ± 0.3 per cent for the complete range of saturations up to 100 per cent. Measurements were made of change in capacitance or frequency change in terms of difference in vernier reading (reading for cell with fluid minus reading for cell without fluid) over the range of saturations from 0 to 100 per cent.

When fluid saturations exceeded 30–40 per cent a slow frequency drift took place, always in the same direction. This was attributed to gravity drainage. When conditions had stabilized, vernier settings could be reproduced for the same fluid saturation to within less than ± 0.1 —the total vernier difference being of the order of 50 divisions, for 0–100 per cent fluid saturation. The overall effect of gravity drainage was to cause a difference of vernier reading of up to 0.4 of a division from the initial reading—this corresponded to a variance in the fluid saturation of up to 5 per cent. Since this distribution of fluid could not be handled quantitatively the readings for a particular fluid saturation were taken at time $t = 0$, that is, before any drainage took place. The effect of gravity drainage on the capacitance or vernier reading is illustrated for a number of fluid saturations in Fig. 2. It can be seen that the system may take as much as one hour to become stable. The curves illustrating the relationship between fluid saturation and capacitance (vernier reading difference) are shown in Fig. 3. It is apparent from the general shape of the curves that the greatest sensitivity of the method is in the regions of low saturation. In addition,

Fig. 2

Fig. 3. $\circ$, 1 000 kc/s., water, - 80 + 40 sand, $\epsilon = 34.3$ per cent; $\triangle$, 500 kc/s., water, - 80 + 40 sand, $\epsilon = 34.8$ per cent; $\square$, 1,000 kc/s., 0.05 N sodium chloride solution, - 80 + 40 sand, $\epsilon = 34.3$ per cent

increase of frequency appears to change the curvature, increasing the extent of the sensitive range. In the case of the 0.05 N sodium chloride solution the curve is displaced in such a manner as to decrease the sensitive range, and at any particular fluid saturation this is an analogous situation to a high-frequency titration, in that changes in concentration are being measured at constant saturation.

Further investigations of this method of measuring fluid saturation in porous media are continuing with the aim of increasing the range of sensitivity by the use of higher frequencies.

GEOPHYSICS

Unidentified Earth Tremors in Dominica, West Indies

TREMORS the origin of which has not been identified were recorded by our seismograph station at Roseau in the volcanic island of Dominica during September 1959, and have been recorded at irregular intervals ever since.

Each tremor consists of an approximately sinusoidal ground motion of 0.3-sec. period. The first swing is always down, the first and eighth swings are maxima and there are about twelve swings in all. The ground amplitude of these maxima varies from about 0.1 μ , which is the point at which the tremors become masked by the microseismic background, to 1.0 μ . They are quite unlike the tremors produced by near earthquakes or by explosions on land or at sea. Factories, quarries and other possible artificial sources for the tremors in Dominica have been investigated and eliminated.

The tremors tend to occur in bursts, numbering from two or three to several hundred tremors, which

may start at any hour of the day or night and continue for periods up to twelve hours. The average period between bursts has been seven days, but there is no evidence of periodicity.

We have operated three additional Willmore-Watts seismographs in Dominica for six weeks in January and February 1960 and have found that the tremors can be recorded only within a few kilometres of the town of Roseau. Because of long quiet periods between bursts of activity, useful recordings were obtained only of a burst of five tremors at one station 1 km. from the Roseau Station and at the Roseau Station itself. There is a possible correlation between the differences in arrival times and the ratios of the maximum amplitudes of the tremors at the two stations, which is consistent with each tremor having originated at a point source and having obeyed an inverse square law of attenuation. Assuming such an attenuation law the amplitudes at the two stations indicate that the sources lie close to a circle of about 5 km. diameter, the northern part of which passes through the town of Roseau. The differences in arrival times at the stations indicate a seismic velocity between 150 m./sec. and 740 m./sec. depending on the locations of the sources on the circle.

Fig. 1 Unidentified earth tremor recorded at the Seismic Research Unit's Seismograph Station at Roseau, Dominica, on September 11, 1959

The town of Roseau is situated on a delta of sand and gravel built by the Roseau River on the steeply shelving east coast of the island of Dominica. In such materials the velocity of longitudinal waves is about 750 m./sec. We have estimated the energy release at the source as about 10^{14} ergs for the largest tremor recorded. The island contains several active thermal areas and ancient centres of eruption, but none is near the apparent sources of the tremors. We can find no evidence that these are related in any way to the volcanic activity of the island; but we cannot put forward an alternative explanation for their origin. We should be grateful to hear from others who have had experience of similar tremors.

CRYSTALLOGRAPHY

Crystal Structure of Orthorhombic Cobalt Molybdate

IN petroleum refinery practice de-sulphurization is carried out by catalysts consisting of an η - or γ -type alumina impregnated with cobalt and molybdenum oxides. However, the nature of the cobalt and molybdenum compound or compounds present on

the catalyst is quite unknown, and a search through the literature reveals that there is almost no information on the formula and crystal structure of cobalt molybdate. A mineral paterite is known which is quoted as having the formula CoMoO_4 .¹

A series of iso-structural normal tungstates of small cations is known² the general formula of which is RWO_4 , where R = cobalt, iron, magnesium, manganese, nickel and zinc, and recently the structure of nickel tungstate has been investigated in detail³. Powder diffraction patterns of laboratory and commercially prepared cobalt molybdate, after heating to 700°C., show that the compound does not possess a structure isomorphous with the tungstate family. However, normal molybdates and tungstates of larger cations, for example, barium, calcium, cadmium, lead and tin, are known and form an iso-structural series, the parent structure being scheelite. In order to provide fundamental information, attempts were made to grow single crystals of cobalt molybdate from a melt of normal sodium molybdate, anhydrous cobalt chloride and sodium chloride as a flux in the ratio of 1:2:2 by weight. The melt was kept at 750–800°C. for 2 hr. and allowed to cool slowly in the furnace. Small yields of crystals were obtained, but the quantities available were too small for accurate analysis. The percentages by weight from chemical and spectroscopic analyses are given in Table 1, leading to an empirical formula of $\text{Co}_2\text{Mo}_3\text{O}_{11}$.

	Table 1	
	Cobalt	Molybdenum
Chemical	21.1	45.8
Spectroscopic	20.1	51.2

Examination of the crystals in polarized light and subsequent X-ray photographs showed that monoclinic and orthorhombic crystals were present, both forms being deep blue in colour and possessing well-marked crystal faces. The monoclinic crystals will not be reported on here. The orthorhombic crystals possessed two well-formed crystal habits which were either long thin needles up to 2 mm. in length by 0.1 mm. $\times$ 0.1 mm. cross-section, or platelets with dimensions up to 1 mm. long $\times$ 0.3 mm. wide but only 0.01 mm. thick, with a pair of edges parallel to the long dimension. X-ray photographs showed that the shortest unit cell axis a was parallel to this dimension and to the needle axis, while the longest unit cell axis c was perpendicular to the plane of the platelet. The crystals showed straight extinction, and an acute interference figure was obtained on (001). The crystals are positive with α parallel to b , β parallel to a and γ parallel to c . No attempt was made to measure $2V$ or any of the refractive indices.

Laue and symmetrical oscillation photographs about all the axes confirmed the orthorhombic symmetry, and from rotation and zero layer Weissenberg photographs using copper $K\alpha$ radiation the unit cell dimensions were calculated: $a = 5.245 \pm 0.003$ Å., $b = 10.778 \pm 0.005$ Å., $c = 18.017 \pm 0.006$ Å., $V = 1018.5 \pm 2$ Å.³. The error is an estimated one.

The density was found to be 3.79 ± 0.05 gm./c.c. by flotation in a solution of thallous malonate and formate, leading to four formula units of $\text{Co}_2\text{Mo}_3\text{O}_{11}$ in the cell. Theoretical density = 3.80 gm./c.c.

Zero and upper-layer Weissenberg photographs about each axis showed that all hkl reflexions were present and that systematic absences were observed for $0kl$ with $(k+l)$ odd and for $h0l$ with h odd. The space group is therefore either $Pn2_1a$ or $Pnma$. A

simple test for pyroelectricity was inconclusive, but the application of intensity statistics⁴ to the principal zones $hk0$, $0kl$, $h0l$ and to all hkl reflexions showed that the distributions were centric. Space group $Pnma$ was therefore adopted.

A crystal fragment 0.3 mm. $\times$ 0.15 mm. $\times$ 0.2 mm. was cut from one of the largest needles, and zero-layer Weissenberg photographs about the three axes and equi-inclination photographs of layers $h = 1$ to 8 about the a axis were taken on molybdenum $K\alpha$ radiation using the multiple film technique. The intensities of all reflexions were measured out to the maximum limit of observation ($\theta \approx 45^\circ$). In all 103 $hk0$, 294 $h0l$, 314 $0kl$ and 2,412 hkl non-zero independent reflexions were measured by visual comparison with a calibrated strip. The intensities were corrected for the Lorentz and polarization factors to give a set of relative $|F|^2$. No absorption correction was applied as the crystal was of optimum size $\mu = 75$ cm.⁻¹. Wilson's method was used for placing the relative $|F|^2$ on an absolute scale and for deriving the temperature factor. $B = 1.29$ Å.².

Patterson projections down the a and b axes, both sharpened and unsharpened, were calculated together with the complete three-dimensional Patterson function. The calculations were made on a Deuce computer using a programme written by Dr. J. S. Rollett (University of Oxford). The three-dimensional Patterson function was calculated over one-eighth of the unit cell at intervals of $u = 1/20$, $v = 1/80$, $w = 1/120$ and plotted in eleven sections parallel to the bc plane. Because of a limitation in the storage on Deuce the number of reflexions was restricted to about 2,350 and the calculation took 8½ hr.

The projection $P(u, w)$ showed special features in that nearly all the peaks were concentrated on the two lines $u = 0$ and $u = \frac{1}{2}$ with a very large peak, 75 per cent of the origin peak height, at $(0, \frac{1}{2})$. Some of the peaks were elongated in the u direction and only two shallow peaks existed elsewhere in the function. It was therefore clear that the cobalt and molybdenum atoms must all lie in or very close to the n glide plane. The projection $P(v, w)$ gave a well-resolved map, but no attempt was made to solve it directly and all the heavy atom co-ordinates were derived from $P(u, v, w)$.

Nearly all the peaks in $P(u, v, w)$ were concentrated in the sections $P(0, v, w)$ and $P(\frac{1}{2}, v, w)$, both of which showed apparent two-fold symmetry, about $(0, \frac{1}{2}, \frac{1}{2})$ and $(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$ respectively, of peak position but not peak height. The absence of peaks at $(0, \frac{1}{2}, 0)$, $(\frac{1}{2}, 0, \frac{1}{2})$ and $(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$ clearly indicated that no heavy atoms were sited on the centres of symmetry. They are therefore either in the general positions or on the mirror plane. Co-Co, Mo-Mo, Co-Mo, Mo-O and Co-O single interaction peaks were scaled in terms of the origin peak, and from a study of all the Harker symmetry vectors for the general and special positions it was possible to derive the co-ordinates of all the heavy atoms. Eight cobalt and eight of the molybdenum atoms were sited in the general positions and the remaining four molybdenum atoms on the mirror plane. The non-Harker vectors were calculated from these co-ordinates, which gave satisfactory agreement between peak heights and positions and accounted for all the major peaks in $P(u, v, w)$.

The co-ordinates are:

		x	y	z
General positions	8 cobalt	0.250	0.075	0.478
	8 molybdenum	0.278	0.017	0.155
Special positions	4 molybdenum	0.278	0.250	0.944

for several hours to establish a film. Then a $\frac{1}{8}$ -in. diameter chrome alloy steel hemisphere was slid over the film at the same speed. Load was increased in 50-gm. increments according to a standard schedule until film failure (metal-to-metal contact or seizure) was indicated by a precipitous rise in friction. Observations were taken in room air at 25° C. within the relative humidity range of 30–40 per cent. The seizure loads attained with a number of additives together with the minimum values of coefficient of friction for the films are reported in Table 1.

Table 1

Additive	Coefficient of friction	Maximum load carried (kgm.)	Additive	Coefficient of friction	Maximum load carried (kgm.)
Sb ₂ S ₃	0.057	5.8	ZrS ₂	0.061	2.3
PtS ₂	0.056	5.5	HgS (black)	0.048	1.8
TiS ₂	0.04	5.4	Tl ₂ S ₃	0.060	1.5
HgS (red)	0.038	5.3	Cr ₂ S ₃	0.08	1.2
Ag ₂ S	0.06	5.3	BaS	0.07	1.0
PbS	0.038	5.2	Tl ₂ S	0.082	0.9
FeS	0.063	4.9	SnS	0.07	0.9
Ti ₂ S ₃	0.065	4.9	CaS	0.15	0.9
Cu ₂ S	0.084	3.9	CdS	0.14	0.8
PbS	0.059	3.6	FeS	0.40	0.8
As ₂ S ₃	0.065	2.8	ZnS	—	0.3
Bi ₂ S ₃	0.045	2.9	MoS ₂	—	0.3
SnS ₂	0.047	2.8			

For the most favourable case the additive increases the seizure load for the film by more than a factor of twenty over that for a pure molybdenum disulphide film. The low friction values indicate that molybdenum disulphide is the lubricant in all cases and that the additives probably take little part in any shearing phenomena. Similar results were obtained when tungsten disulphide was the lubricant in place of molybdenum disulphide. For substrates harder than mild steel (for example, 1090 steel, chromium plate) the seizure loads observed are even greater.

The action of these additives in solid lubricants resembles that of the extreme pressure additives for liquid lubricants. A chemical role is assigned to such additives, and a similar mechanism may explain the behaviour of additives in solid lubricant films. However, evidence to support this hypothesis is indirect. Where thermodynamic data are available, the most effective additives tend to have the lowest stability. Films of molybdenum disulphide have higher load-carrying ability if they are applied to mild steel surfaces on which a surface film of ferrous sulphide has been formed by chemical reaction. Chemical analyses indicate that an active additive tends to be more concentrated in a rubbed film than in the rider from which the film was rubbed.

Though the hypothesis of chemical attack by the additives is attractive, the results do not preclude the possibility that effects other than chemical are important in enhancing the adhesion of the film to the metal substrate.

It is planned to publish a more detailed account of this work elsewhere.

RADIATION CHEMISTRY

Effect of X-Rays on Cytosine in Aerated Aqueous Solution

WHILE X-irradiation of aqueous solutions of thymine and uracil in an atmosphere of air gives rise to high yields of hydroperoxides¹⁻³, X-irradiation of cytosine under similar conditions does not give more than traces of hydroperoxides in our hands.

However, ion exchange chromatography of cytosine solutions irradiated with X-rays under air or oxygen (1 atm.) separates three degradation products, which are not detected when the solutions have been irradiated under nitrogen. A typical elution diagram is shown in Fig. 1, giving the positions of these three products, designated as A, B and C, and of unchanged cytosine. Product C and cytosine are detected by measuring the optical densities of the chromatographic fractions at 300 m μ and at 275 m μ , respectively. Products A and B are not detected under these conditions, since they do not absorb strongly at these wave-lengths; but if the fractions containing them are first boiled for 30 sec., their optical densities at 275 m μ increase to give the figures plotted in Fig. 1, products A and B being transformed by heating into compounds with high absorption coefficients at this wave-length.

Fig. 1. Ion exchange chromatography of X-irradiated cytosine. Cytosine solution: 10^{-3} M in water, 40 ml., irradiated in the presence of air at room temperature. X-rays: 40 kV., filtered through 0.04 mm. aluminium; dose-rate: 25 kr./min.; dose = 150 kr. Chromatography on Dowex 50, H⁺ (125 cm.), elution with 2 N hydrochloric acid at room temperature; fraction volume: 3 ml. —, Optical density at 275 m μ ; ---, optical density at 300 m μ . Fractions 1–16 have been heated to boiling.

Product C has been compared with synthetic 2,5-dioxo-6-aminopyrimidine (6-amino-*iso*-barbituric acid), prepared according to Johnson *et al.*⁴. The ultra-violet absorption characteristics of product C and of 6-amino-*iso*-barbituric acid are recorded in Table 1. The two compounds cannot be separated from each other by paper chromatography (Table 2) or by ion-exchange column chromatography. By heating product C in a sealed tube at 175° for 4 hr., a compound is formed having the absorption spectrum (Table 1) and the chromatographic behaviour (Table 2) of synthetic *iso*-barbituric acid, obtained by deamination of 6-amino-*iso*-barbituric acid under the same conditions⁴. All these results allow us to conclude that product C actually is identical with 6-amino-*iso*-barbituric acid. Under the conditions

of the experiment described in Fig. 1, the yield in product *C* is $G = 0.34$.

When product *A* is heated to boiling in 2 *N* hydrochloric acid, the resulting compound has the same ultra-violet spectrum (Table 1) and the same chromatographic behaviour on paper chromatograms (Table 2) as *iso*-barbituric acid. The yield in product *A*, estimated after transformation to *iso*-barbituric acid, is $G = 0.20$. When product *B* is similarly heated, ion exchange chromatography of the resulting solution separates two products *B*₁ and *B*₂. Product *B*₁, which is much more abundant than *B*₂, has the same ultra-violet spectrum (Table 1) and the same chromatographic behaviour (Table 2) as *iso*-barbituric acid. *B*₂, on the other hand, has the same spectral and chromatographic properties as 6-amino-*iso*-barbituric acid. If product *B* is heated at a nearly neutral pH, the same compounds are also produced, but the yield in the 6-amino one is increased relatively to that of the free acid. Since products *A* and *B* have no absorption bands between 250 and 300 mμ, their 4,5 bond is presumably saturated. *B* differs from *A* by having a 6-amino group, which is more easily lost than the amino group of 6-amino-*iso*-barbituric acid. It can be recalled in this respect that Green and Cohen⁵ have already shown that 4,5-dihydrocytosine is very easily deaminated.

When synthetic 6-amino-*iso*-barbituric acid itself is X-irradiated in the presence of air (10⁻³ *M* solution receiving 300 kr.), *iso*-barbituric acid is formed, but no product *B*.

We think that the preceding experimental results can best be explained by assuming that products *A* and *B* have the formula shown in Fig. 2, and are

CHEMISTRY

Use of Chlorine in the Detection of Compounds on Paper Chromatograms

Rydon and Smith¹ described a sensitive method for the detection of amino- and imino-compounds on paper chromatograms: the method consisted of exposure of the dried chromatograms to an atmosphere of chlorine, followed by aeration to remove 'background' chlorine, and detection of the resultant chloramines by liberation of iodine from a starch/

potassium iodide reagent. In Reindel and Hoppe's modification² of the procedure, the chromatograms were moistened with an acetone/alcohol mixture and exposed to gaseous chlorine in a tank before detection of the chloramino derivatives with a toluidine/potassium iodide reagent. In a further modification³, the chromatograms were moistened with steam, exposed to gaseous chlorine, heated briefly to 50° and developed with the toluidine/potassium iodide reagent.

In our hands, both the chlorination and aeration stages of the original procedure¹ proved difficult to standardize. Prolonged aeration, which had a variable effect on the chloramino derivatives, was sometimes required to remove background chlorine. It seemed that this was necessary when the tank atmosphere was particularly humid; on these occasions, and in Smith's procedure³, the paper presumably retained a layer of chlorine water which had to be removed by aeration, or by heating to 50°, in order to obtain a satisfactory background. The need for water in the chlorination process was suggested by unsuccessful attempts to detect nitrogenous compounds using dry carbon tetrachloride saturated with chlorine as the chlorinating reagent (unpublished results).

In preliminary attempts to replace the inconvenient tank procedure by a reliable spray reagent, different effects were observed, which were used to advantage in the procedures to be described. The spray reagents were prepared by dilution of a sodium hypochlorite solution (10–14 per cent w/v) or a potassium chlorate/hydrochloric acid reagent⁴, and were applied to dried chromatograms using about 1 ml./50 cm.². In procedure (a) the chromatogram was sprayed with sodium hypochlorite solution diluted 1:150, and then left for 45 min. at room temperature. In procedure (b) the chromatogram was sprayed with sodium hypochlorite solution diluted 1:25, left 45 min. at room temperature and heated for 5 min. at 55°. In procedure (c), the chlorate/hydrochloric acid reagent was diluted 1:10 and, after spraying, the chromatogram was left for 45 min. at room temperature before heating for 15 min. at 55°. Chromatograms treated in this way were developed by immersion in a toluidine/potassium iodide reagent⁵.

The effect of these procedures on a variety of sugar derivatives is shown in Table 1. It can be seen that procedure (a) located only amino-compounds, whereas procedure (b) located both amino- and imino-compounds. This provided a convenient method for distinguishing amino- and imino-compounds which was particularly useful with compounds reacting poorly with ninhydrin (for example, the anomeric

1:3:4:6-tetra-O-acetyl-2-amino-2-deoxy-D-glucose hydrochlorides, unpublished results).

On chromatograms developed immediately after spraying with hypochlorite, the blue spots generated by the chloramino derivatives could be distinguished only with difficulty from the dark background. The success of procedures (a) and (b) depended on being able to reduce this background colour without affecting seriously the chloramino derivatives. Certain compounds, however, showed as white spots against a blue background, indicating the removal of hypochlorite and the formation of products unable to react with the toluidine reagent. It appeared that, in contrast to tank chlorinations, the amount of chlorinating agent in the spray reagents was the limiting factor. Procedure (c), which used the more easily controllable chlorate/hydrochloric acid reagent to generate the background colour, was based on this effect. Table 1 shows that whereas compounds with a benzene nucleus or a reducing group (for example, phenyl β -D-glucoside, glucose) were detected, the result given by compounds containing one of these groups together with an amino- or imino-group depended on the reactivity of the groups present: the results in Table 1 indicated reactivities in the order phenyl > amino > imino > reducing group. Procedure (c) was the most sensitive method for the detection of some compounds, particularly the anomeric phenyl 2-acetamido-2-deoxy-D-glucosides⁶.

Other chlorinating agents (for example, 'Chloramine-T', chlorine water) and other indicator systems (for example, starch/potassium iodide, diphenylamine, *o*-phenanthroline) were tried, but none proved so satisfactory as those described. The three procedures are reproducible and can be used for the detection of a wide range of nitrogenous, aromatic and reducing compounds on paper chromatograms. However, care may be necessary in the selection and removal of chromatographic solvents, since some of these may interfere with the detection procedures (cf. Reindel and Hoppe¹).

A Split-Temperature Column System for Gas Chromatographic Analyses

THIS communication describes a simple but effective improvement on the speed and resolution in gas chromatographic analyses by means of a split-temperature column system which has provisions for two or more different temperature regions in the same unit and which provides a means of changing rapidly the temperature in these various regions (patent applied for). Such a system possesses the combined advantages of a single low-temperature system, a single high-temperature system, as well as a temperature-programmed system¹, and, usually,

Fig. 1. Gas chromatogram with split-temperature column. Note short time, good resolution and well-defined peaks

can result in an appreciable reduction of the time required for each analysis.

Consider the analysis of a mixture containing both high- and low-boiling components. If a single low-temperature column is used, the time required to resolve the low-boiling components is sometimes unnecessarily long without any gain in resolution, whereas the high-boiling components are either held back even after a very long time, and thus cannot be detected at all, or are detected only as extremely broad peaks which cannot be accurately measured. If only a high-temperature column is used, the high-boiling components can form well-defined peaks; but the resolution of the low-boiling materials may become too poor and not useful. A manually temperature-programmed column requires considerable attention by the operator, and can give reproducible retention results only if the analysis is carried out with great care. A linear temperature-programmed system is, at least for the present, still rather expensive, and also requires longer time for analysis than the split-temperature system.

In our preliminary experiments, we used a steel enclosure consisting of seven sections individually heated by heating tapes and controlled by bimetallic thermo-regulators. These sections were partly insulated from each other by glass wool packings, and partly connected with each other by metal strips, providing thereby a sufficiently uniform temperature within each section, and a reasonably smooth temperature gradient between sections. A 10-ft. glass column, packed with 'Apiezon-L' on firebrick, and connected to a 'Burrell Kromotog-K-1', completed the chromatographic system. A mixture, consisting of (i) *n*-pentane, (ii) benzene, (iii) methyl cyclohexane, (iv) toluene, (v) *o*-xylene, (vi) *m*- and *p*-xylene, (vii) ethyl benzene, (viii) *n*-propyl benzene, (ix) *i*-propyl benzene, (x) *t*-butyl benzene and (xi) *t*-butyl toluene, formed the analytical sample. In operation, portions of the column were kept initially at lower temperatures so that there would be adequate resolution for the low-boiling components, and the remainder of the column was kept at the higher ultimate temperature. After the lower-boiling components had been eluted, the whole column was

brought to the ultimate temperature for the analysis of the higher-boiling substances.

A series of experiments with the various sections having different initial temperatures ranging from 120° to 180°, and an ultimate temperature of 180°, have been carried out. For the purpose of comparison, the column was also heated uniformly at 130° and at 180° only, and the corresponding chromatograms were also obtained. It was found that, for the case when the column was heated uniformly at 130° C., although the low-boiling components (i-vi) were satisfactorily resolved, the peaks for the higher-boiling components (vii-x) were ill-defined and that the peak for the highest boiling component (xi) was not detectable within a period of 1½ hr. For the case when the column was heated uniformly at 180° C., the total time

required for the 11 components was 14 min.; but the resolution of components (v) and (vi) and components (vii) and (viii) was very poor and not useful. In contrast, the split-temperature column system permitted the separation of all eleven components in a time-period of 20 min. with the resolution of the low-boiling components comparing favourably with those obtained by the low-temperature column, and the resolution of the high-boiling components comparing favourably with those obtained by the high-temperature column. This is illustrated in Fig. 1, which shows clearly the satisfactory performance of the split-temperature system from the points of view of both the short time required for analysis and satisfactory resolution.

A split-temperature column system can be constructed easily and inexpensively with readily available components, and should be usable with most of the existing gas chromatographs. It permits the analysis of a larger number of samples per chromatograph, and also permits the use of one single long column for each type of packing since the effective length of a column now can be conveniently varied by changing the length of the lower-temperature portions of the column.

Separation of Sphingosine and Dihydrosphingosine by Reversed Phase Paper Chromatography

THE isolation of dihydrosphingosine from cerebro-sides of beef brain and spinal cord by Carter *et al.*¹ raised questions regarding its distribution in different sphingolipids and its metabolic relationships to sphingosine. However, no method for the routine

Fig. 1. Chromatogram showing the dinitrophenyl derivatives of O-methylsphingosine (1), dihydrosphingosine (2), sphingosine (3) and crude base fraction (CB). (4) is dinitrophenol

differentiation of sphingosine and dihydrosphingosine appeared until very recently with the gas chromatographic method of Sweeley and Moscatelli². Wittenberg³ separated the N-succinyl derivatives of sphingosine and related compounds by reversed phase chromatography on diatomaceous earth treated with dichlorodimethylsilane, but he was unable to separate sphingosine and dihydrosphingosine. This communication describes a reversed-phase paper chromatographic method for the separation of the dinitrophenyl derivatives of sphingosine and dihydrosphingosine.

A crude fraction of sphingolipid long-chain bases was prepared principally according to Carter *et al.*¹. 1–5 mgm. of the bases were transferred to their dinitrophenyl derivatives by keeping them for 30 min. in 4 ml. of a potassium borate buffer, pH 10, containing 2 μ l. fluorodinitrobenzene in 1 ml. ethanol at 60° C. The derivatives were extracted with diethyl-ether and 5–15 μ gm. were applied with a micropipette to Whatman paper 3MM on a line 2 cm. from the bottom of the paper. The paper was sprayed almost to transparency with the stationary phase of tetralin down to a line 1 cm. above the line of the derivatives. The paper was then immediately run in methanol/triethylamine/water (85 : 5 : 10 v/v) saturated with tetralin in the ascending direction for 17 hr. at room temperature. The spots were read under ultra-violet light and the R_F values obtained were for dinitrophenyl-O-methylsphingosine 0.20, dinitrophenyl-dihydrosphingosine 0.36, dinitrophenyl-sphingosine 0.44 and dinitrophenol 0.87 (Fig. 1). The R_F values of dinitrophenyl-O-methylsphingosine and dinitrophenyl-O-methyldihydrosphingosine differed only little and the spot of dinitrophenyl-O-methylsphingosine therefore also contained dinitro-

phenyl-O-methyldihydrosphingosine. Dinitroaniline, which was only just traceable, had an R_F value of 0.71. Authentic samples of triacetylsphingosine, tribenzoyldihydrosphingosine and O-methylsphingosine sulphate, which were gifts from Dr. Carter, University of Illinois, were after hydrolysis used as references for the identification of the bases.

These were further indirectly identified by the following procedures. The dinitrophenyl-O-methylsphingosine spot disappeared after changing the hydrolysis in the isolation procedure from methanolic to aqueous sulphuric acid. Sphingosine and dihydrosphingosine were precipitated from the base fraction according to Carter *et al.*⁴. After hydrogenation of the bases with platinum oxide as catalyst the dinitrophenyl-sphingosine spot disappeared and the dinitrophenyl-dihydrosphingosine spot was correspondingly enlarged.

Structure of the Trinuclear Titanium (IV) Alkoxides

THE association of *n*-alkoxy derivatives of orthotitanic acid was first established as recently as December 1951 by Caughlan *et al.*¹. Cryoscopic determinations of molecular weight in freezing benzene revealed that $Ti(OC_2H_5)_4$, $Ti(OC_3H_7)_4$ and $Ti(OC_4H_9)_4$ were all trimeric except at very high dilutions when dissociation to the monomer was observed. The association was ascribed to the strong tendency of quadrivalent titanium to attain a six-covalent oxygen environment, as, for example, in rutile or anatase. Caughlan *et al.* suggested that this could be achieved if each pair of titanium atoms was supported by three bridging alkoxy-groups giving two alternative structures I and II, which were based on the stacking of three TiO_6 -octahedra face to face. Structure II necessitates a four-co-ordinated square planar oxygen atom attached to three titanium atoms and one alkyl group, and for this reason is considered by us to be untenable.

Structure I has been widely accepted² as the basis on which to interpret the chemistry of titanium (IV) alkoxides, and, in particular, the group working at Birkbeck College³ have stressed this arrangement when discussing the hydrolysis of these compounds. In fact, they have claimed that the synthesis of polymeric oxide alkoxides (structure IV), built up by cross-linking trimer units with structure I through Ti-O-Ti bridges, "appears to be unique and justifies exclusive consideration".

The purpose of this communication is to indicate that at least two other stereochemical arrangements are possible, which we believe are in better agreement with the available experimental data. The first of these is again based on a six-covalent oxygen environment for titanium, but a trigonal prismatic rather than an octahedral arrangement of the TiO_6 -group is envisaged. This leads to structure III in which two 'bridge' and two 'terminal' alkoxy-groups per

(I) $Ti_3(OR)_{12}$. ●, Ti; ○, O in OR(II) $Ti_3(OR)_{12}$. ●, Ti; ○, O in OR

titanium atom are present. A geometrical model reveals that twelve *n*-alkyl groups can be nicely accommodated about the three titanium nuclei without steric hindrance. We believe that an important advantage of structure III lies in its natural symmetry, in contrast with structure I, in which the central titanium atom is surrounded by six alkoxy bridges with the other titanium atoms each carrying three terminal and three alkoxy bridges. The need for a high degree of symmetry in these compounds is reflected, for example, in the inter-

(III) Proposed cyclic structure for $Ti_3(OR)_{12}$ based on TiO_3 -trigonal prisms(IV) $Ti_4O_4(OR)_{12}$. ●, Ti; ○, O in OR; ●, O in $Ti-O-Ti$

pretation of the molecular complexity of chlorine-substituted alkoxides. Thus, in agreement with Caughlan *et al.*, we also find that monochloro-titanium (IV) butoxide is trimeric. A symmetrical structure for $Ti_3Cl_3(OC_4H_9)_3$, based on structure I is not possible, but follows naturally from structure III, which can accommodate one terminal chlorine atom per titanium. Similarly, the hydrolysis reactions of titanium (IV) alkoxides become much more amenable to a reasonable kinetic interpretation. For example, the careful studies of Bradley, Gaze and Wardlaw⁴ have resulted in the isolation of $Ti_6O_4(OR)_{16}$ as the product of the first stage of hydrolytic polymerization of $Ti_3(OR)_{12}$, for which they propose structure IV. A polymerization of this kind would appear to require a statistically unfavourable mutual orientation of two $Ti_3(OR)_6(OH)_4$ units before effective collision and expulsion of four water molecules could occur, and would also require the preferential hydrolysis of two terminal and two bridging alkoxy groups from only one side of the trimer. Furthermore, it also involves an unknown four-covalent bonding arrangement between oxygen and its nearest four titanium neighbours.

We suggest that the hydrolysis of $Ti_3(OR)_{12}$ with structure III can be formulated without raising the above difficulties, and yet can lead logically to oxide-alkoxide polymers of the type $Ti_6O_4(OR)_{16}$, $Ti_3O_2(OR)_{10}$ and $Ti_2O_3(OR)_{14}$ reported by the Birkbeck school. The hydrolysis of terminal alkoxy groups, the intermolecular elimination of alcohol, and the intramolecular elimination of water appear to be likely successive stages. Such a mechanism involves a kinetically simple two-point collision, and a possible scheme would be as follows (*b* = bridge; *t* = terminal group):

The terminal $Ti=O$ groups formed involve five-covalent titanium, and in this connexion the recent work of Andersson and Wadsley⁵ is particularly relevant, since these workers have established that quadrivalent titanium in the mixed oxide $K_2Ti_2O_5$ is five-covalent. In a personal communication, they have suggested to us structure V, which is based on a trigonal bipyramidal TiO_5 -grouping, as an alternative configuration for $Ti_3(OR)_{12}$. This differs from structure III, not only in the five-covalency of titanium, but also in that only one alkoxy-bridge per titanium atom is present.

(V) Alternative cyclic structure for $Ti_3(OR)_{12}$ based on TiO_5 -trigonal bipyramids

We believe that the known behaviour of titanium (IV) alkoxides and the chloro-alkoxides is in better agreement with a cyclic than a linear arrangement of the three titanium atoms. Whether the titanium is five- or six-covalent must rest on a complete structure analysis. It is quite conceivable that in the pure state or in benzene solution, titanium exhibits five-covalency, but under the influence of a strong solvating medium such as butanol, expansion to six-covalency takes place.

A more detailed account of this work will be published elsewhere.

Heat Treatment of Irradiated Polypropylene

It has been shown by Lawton^{1,2} that during the high-energy irradiation of a polymer, the main effect produced is either intermolecular cross-linking or degradation of the molecular chain, and radicals produced during irradiation can be trapped in the crystalline regions. Crystalline 'Marlex-50', irradiated at 25° C. and then annealed at 150° C., gave more cross-links than 'Marlex-50' irradiated at 25° C. and not annealed, but less than that of the polymer irradiated at 150° C. for the same dose of irradiation. We have been able to demonstrate the delayed cross-linking effect by heat treatment of pre-irradiated isotactic polypropylene. We find that many trapped radicals produced during irradiation, which are stable at room temperature (as detected by electron spin resonance measurements), could contribute to delayed cross-linking on annealing the irradiated polymer after irradiation, and a big increase of gel content was observed. On the other hand, materials irradiated at 180° C. (molten state) gave no gel content for high dosage beyond 80 Mrads, indicating that in the molten state degradation of the molecular chain was predominant. The phenomenon is very different from the effect in polyethylene.

Isotactic polypropylene ('Moplen') powder was used. The molecular weight determined from viscosity was 2.7×10^5 . The degree of crystallinity is reported to be 75 per cent. Rods were prepared by melting the powder in the glass ampoule under high vacuum. The materials were irradiated at 25° C. (in the crystalline state) and at 180° C. (in the molten state) in glass ampoules under a vacuum of less than 10^{-5} mm. mercury with γ -rays from a 1,000-curie cobalt-60 source; the irradiation intensity was 3.0×10^5 rads/hr.

In some experiments, polypropylene powder was irradiated in air. The polypropylene rods pre-irradiated *in vacuo* were annealed for an hour in a vacuum at the temperature-range 100–230° C. in an oil-bath soon after irradiation without exposing them

to air. The powder irradiated in air was annealed at 150° C. for an hour in a vacuum.

Solubility measurement to determine gel content was used as a measure of the relative cross-linking effectiveness of the irradiation. The cross-linking gel fraction was determined by measuring the insoluble fraction extracted by suspending the irradiated samples (or samples annealed after irradiation) in a large volume of boiling tetraline at 207° C. for 48 hr. After extraction, the materials were immersed in hot methanol for different times, and traces of solvent in the materials were removed, vacuum dried and weighed.

In the case of isotactic polypropylene, the delayed cross-linking effect by heat treatment of pre-irradiated polymer is very conspicuous (Table 1).

Table 1. GEL CONTENT (PER CENT) OF IRRADIATED POLYMERS

Irradiation dosage	13 Mrads	83 Mrads
Irradiation at 25° C. <i>in vacuo</i>	0	47
Irradiation at 180° C. <i>in vacuo</i>	0	0
Irradiation at 25° C. in air	0	0
Irradiation at 25° C. <i>in vacuo</i> , and then annealed at 180° C. <i>in vacuo</i>	34	72

The gel content of irradiated polymers under various conditions is shown in Table 1. Irradiation dosages were 13 Mrads or 83 Mrads. The gel content of the specimen annealed at 180° C. after irradiation was much higher than that of unannealed.

The observations indicate that trapped radicals in the crystal could move to form intermolecular cross-links. When irradiated at 180° C. (amorphous molten state), the specimen gave no gel content with even 83 Mrads, indicating that scission of the main chain is more important here than cross-linking.

In Fig. 1 the relations of the delayed cross-linking effect to annealing temperature in the case of pre-irradiation dosages of 13 Mrads and 83 Mrads are shown. In both cases, gel content increases rapidly in the temperature range of the melting point, due to the mobility of the trapped radicals in the crystal. The relation of the sol fraction S of specimen irradiated at 25° C. *in vacuo*, and of the specimen irradiated at 25° C. *in vacuo* and then annealed at 150° or 180° C. *in vacuo*, to irradiation dosages is shown in Fig. 2.

Charlesby's formula³ can be applied to the results:

$$S + \sqrt{S} = p_0/q_0 + 1/q_0 U_1 R$$

in which p_0 is the probability of degradation of a molecular chain by unit irradiation, q_0 is the probability of cross-linking by unit irradiation, U_1 is number average degree of polymerization, and R is irradiation dosage (in megarads). Assuming the initial

Fig. 1. Gel content of specimens annealed at various temperatures. Dosage: O, 8.7×10^5 rads; Δ, 1.3×10^5 rads

Fig. 2. O, Irradiated at 25° C.; X, irradiated at 25° C. then annealed at 150° C.; Δ, irradiated at 25° C. then annealed at 180° C.

distribution is random, the ratio p_0/q_0 and cross-linking efficiency G_c (number of cross-linking per 100 eV. absorbed) could be calculated from the results.

In the case of irradiation at 25° C., p_0/q_0 was 0.8, and G_c was 0.1, and in the case of annealing at 180° C. after irradiation, p_0/q_0 was 0.7 and G_c was 0.16. During pre-irradiation in the air, a considerable amount of peroxide* might be formed in the polymers. By annealing the pre-irradiated materials at 150° C., these peroxides are decomposed into the radicals which produce intermolecular cross-linking.

Table 2. GEL CONTENT OF THE MATERIALS PRE-IRRADIATED IN THE AIR AND THEN ANNEALED AT 150° C. *in vacuo*

Irradiation dosage (Mrads)	Gel content (per cent)
18	6.0
29	12.1
52	10.2
102	0

In Table 2 the gel content of annealed material pre-irradiated in the air for various dosage is shown. The gel content decreases beyond 50 Mrads because of rapid decrease of molecular weight during pre-irradiation in the air.

BIOCHEMISTRY

Oxidation of Human Haemoglobin by Vitamin K₃

PREVIOUS work in this laboratory has given support to the conclusion that the brain lesion in neonatal bilirubin encephalopathy or kernicterus is primarily due to a toxic effect of free bilirubin on cellular energy metabolism¹. Haemolytic diseases in new-born children, resulting in severe hyperbilirubinaemia, may therefore lead to the development of kernicterus, regardless of the cause of the haemolysis.

Among exogenous factors inducing haemolysis in new-born babies, vitamin K₃ or menadione (2-methyl-

Fig. 1. Oxidation of human haemoglobin by vitamin K₃. 0.05 mM haemoglobin in 0.05 M potassium phosphate buffer, pH 7.5. Curve 1, before addition of vitamin K₃; Curve 2, 5 min. after addition of 1.3 mM vitamin K₃; Curve 3, 10 min. after addition of 1.8 mM vitamin K₃; Curve 4, 42 min. after addition of 1.8 mM vitamin K₃; Dotted curve, after addition of an excess of potassium ferricyanide. Vitamin K₃ was dissolved in ethanol and added in a volume of 0.1 ml. to a final volume of 3 ml. The measurements were carried out in a Beckman DK2 recording spectrophotometer, using glass cuvettes of 1 cm. light-path.

1,4-naphthoquinone), and some of its water-soluble derivatives (for example, synkavit), have recently been paid particular attention. These compounds are widely given to new-born children, and especially to premature infants, in order to improve their capacity to maintain adequate prothrombin titres. Zbinden *et al.*², who have recently reviewed the pertinent literature, have shown that injection of sublethal doses of vitamin K₃ into dogs leads to severe haemolysis, accompanied by haemoglobinuria and haemoglobinæmia. No such effects were obtained with vitamin K₁.

In the present communication it is shown that vitamin K₃, but not vitamin K₁, oxidizes human haemoglobin to methaemoglobin *in vitro*. It was observed that samples of whole blood, suspensions of washed erythrocytes, or erythrocyte-haemolysates, when incubated in the presence of moderate concentrations of vitamin K₃, soon turned dark-brown, whereas vitamin K₁ induced no similar shift in colour. The phenomenon was afterwards investigated by adding vitamin K₃ to a solution of crystalline human haemoglobin prepared according to Drabkin³, and following the colour-shift with repeated scanning in a Beckman DK2 recording spectrophotometer. As shown in Fig. 1, the spectral change consisted of the

Fig. 2. Time-course of oxidation of haemoglobin by vitamin K₃. Comparison of effects of vitamin K₃ and vitamin K₁. Haemoglobin (Hb) and vitamin K₃ or K₁ were added in concentrations as indicated. Other experimental conditions as in Fig. 1. Vitamin K₁ was dissolved in ethanol and the solution was mixed with a small amount of 'Tween-20' to prevent separation of the vitamin K₁ on addition to the test system.

appearance of an absorption maximum at 630 mμ, a decrease of the two maxima at 577 and 541 mμ, and a shift of the absorption minimum at 510 mμ toward a maximum at 500 mμ, all these changes being typical of the transition of oxyhaemoglobin into methaemoglobin⁴. The dotted line in the figure shows the spectrum of 100 per cent methaemoglobin, obtained by adding an excess of potassium ferricyanide to the cuvette.

As is already seen from Fig. 1, the reaction was not linear with time, the rate of methaemoglobin formation decreasing on prolonged incubation. The kinetics of the reaction were studied in more detail by measuring the increase in optical density at 630 mμ as a function of time. Fig. 2 shows that the rate of reaction is dependent on both the concentration of haemoglobin and the concentration of vitamin K₃. From the curves in Fig. 2 it can be estimated that $1.3 \times 10^{-3} M$ vitamin K₃ oxidizes roughly 25 per cent of the haemoglobin present in 7 min. A more detailed study of the kinetics of the reaction was complicated by the reoxidation of the reduced vitamin K₃ by molecular oxygen, with the formation of hydrogen peroxide. Addition of substantial amounts of reduced vitamin K₃ to oxyhaemoglobin caused an immediate colour-shift due to the removal of oxygen, followed by a gradual oxidation of the haemoglobin to methaemoglobin largely according to the kinetics shown in Figs. 1 and 2. Synkavit, the diphosphate ester of reduced vitamin K₃, had no effect on haemoglobin under the present experimental conditions. However, this does not exclude a possible effect *in vivo*, where synkavit may undergo enzymic dephosphorylation.

It is also shown in Fig. 2 that vitamin K₁ caused no oxidation of haemoglobin, even when added in a concentration that in the case of vitamin K₃ gave a relatively rapid oxidation.

Although the relevance of these findings to the problem of the haemolytic effect of vitamin K₃ may not be obvious, there might exist some relation between the two phenomena. It is generally considered that haemolysis is in some way related to a deficient ability of the erythrocyte to maintain its normal level of reduced glutathione⁵. Methaemoglobin has been reported to oxidize reduced glutathione non-enzymically⁶. Furthermore, the reduction of glutathione in the erythrocyte is mediated by glutathione reductase, with reduced triphosphopyridine nucleotide as the specific hydrogen donor⁷. This latter compound is also utilized in the erythrocyte for the reduction of methaemoglobin, by way of a reduced

triphosphopyridine nucleotide-specific methaemoglobin reductase⁸. An increased rate of formation of methaemoglobin, for example, due to vitamin K₃, may therefore constitute an increased competition for reduced triphosphopyridine nucleotide, thus rendering difficult the maintenance of glutathione in the reduced form. In fact, Zinkham and Childs have reported that incubation of neonatal and of primaquine-sensitive erythrocytes with vitamin K₃ resulted in a serious decrease of the level of reduced glutathione⁹.

The above hypothesis is not in conflict with the often-emphasized fact that haemolysis and methaemoglobinemia do not necessarily go hand-in-hand¹⁰, since the capacity of the methaemoglobin reductase system may be sufficient for maintaining a normal level of haemoglobin even at an enhanced rate of haemoglobin oxidation; besides, this reaction seems not to be fully dependent on reduced triphosphopyridine nucleotide, there being also a diphosphopyridine nucleotide-specific methaemoglobin reductase¹¹. Glutathione reduction, on the other hand, may seriously suffer in capacity when methaemoglobin formation, and thus the drainage of reduced triphosphopyridine nucleotide, is increased, especially in cases, as in new-born children or in primaquine-sensitive patients, where the capacity to maintain the level of reduced glutathione seems to be insufficient.

We wish to thank Dr. Andrew Sass-Kortsak, Toronto, for stimulating discussions, and the F. Hoffmann-La Roche and Co., A.-G., Basel, for the preparations of vitamin K used in this work.

2-Hydroxycæstrogens

RECENT work in several laboratories indicates that 2-hydroxylated cæstrogens may be important metabolites of these naturally occurring steroid hormones. Thus King^{1,2} has shown that oestriol is converted into 2-hydroxycæstriol and 2-methoxycæstriol by incubation with rat liver preparations in the presence of molecular oxygen. Work on the oxidation of di- and triphosphopyridine nucleotides by phenolases with oxygen, induced by natural and synthetic phenolic

oestrogens³, clearly demonstrates that *o*-diphenols are involved in this system. Mueller⁴ has claimed that formate incorporation into uterine tissue is increased by the addition of *o*-hydroxylated derivatives of oestradiol *in vitro*. Finally, 2-methoxyoestrone^{5,6} and 2-methoxyoestriol⁷ have been isolated from human urine. It is therefore of importance to devise practical syntheses of the 2-hydroxyoestrogens, in order to facilitate further biochemical and biological investigations.

Mueller has outlined a procedure for the preparation of 2- and 4-hydroxyoestradiol via 2- and 4-nitro-oestrone, but has given no experimental details or physical constants for the intermediate or final compounds. Recently the partial synthesis of 2-hydroxy-oestradiol, starting from 19-nortestosterone-17 β acetate, has been described by Axelrod and Rao⁸. A method for *o*-hydroxylation of phenols due to Loudon and Scott⁹ has been employed by Fishman¹⁰ to convert oestradiol-17 β into 2-methoxyoestradiol-17 β and 2-methoxyoestrone. This method has now been adapted to the partial synthesis of 2-hydroxyoestradiol 17 β and 2-hydroxyoestrone from oestradiol-17 β , and to 2-hydroxyoestriol from oestriol.

Oestradiol-17 β was converted into 2-hydroxy-17 β -acetoxyoestradiol-3-(2-benzoyl-4-nitrophenyl) ether by Fishman's method, and this ether was cleaved with boiling piperidine. The reaction mixture, after separation by chromatography on silica gel, afforded 2-hydroxyoestradiol-17 β acetate, m.p. 181°. Hydrolysis with cold *N* sodium hydroxide in nitrogen gave 2-hydroxyoestradiol-17 β , m.p. 161–162°, $\lambda_{\text{max}}^{\text{EtOH}}$ 289 m μ (ϵ , 4,187), $\lambda_{\text{min}}^{\text{EtOH}}$ 254 m μ (ϵ , 543), $[\alpha]_D^{19}$ + 89° (ethanol), $\nu_{\text{max}}^{\text{Nujol}}$ 3,350 (broad), 1,600, 1,510 cm⁻¹. (Found: C, 75.15; H, 8.3. Calculated for C₁₈H₂₄O₃: C, 75.0; H, 8.4 per cent.)

Treatment of 2-hydroxyoestradiol-17 β with exactly 2 moles of acetic anhydride in dilute pyridine solution at 0° gave predominantly the 2,3-diacetate, m.p. 106–107°, isolated by chromatography on alumina. The infra-red spectrum showed a single, intense, ester band at 1,760 cm⁻¹. Chromium trioxide in acetone-sulphuric acid smoothly oxidized this secondary alcohol to 2,3-diacetoxyoestrone, m.p. 170–171°. Hydrolysis as before yielded 2-hydroxyoestrone, m.p. 193–194°, $\lambda_{\text{max}}^{\text{EtOH}}$ 289 m μ (ϵ , 4,296), $\lambda_{\text{min}}^{\text{EtOH}}$ 255 m μ (ϵ , 527), $[\alpha]_D^{19}$ + 160° (ethanol), $\nu_{\text{max}}^{\text{CHCl}_3}$ 3,550 (sharp) and 3,250 (broad), 1,635, 1,600 cm⁻¹. (Found: C, 75.55; H, 7.9. Calculated for C₂₀H₂₂O₃: C, 75.5; H, 7.75 per cent.)

Oestriol was condensed with 2-chloro-5-nitrobenzophenone to give the 3-(2-benzoyl-4-nitrophenyl) ether, m.p. 130°, which yielded the 16,17-diacetate, m.p. 84–85°, with acetic anhydride in boiling pyridine. Cyclization of the diacetate with cold, concentrated sulphuric acid, followed by oxidation with hydrogen peroxide in acetic acid, gave the 2-hydroxy-3-ether. The latter was cleaved with boiling piperidine, and after chromatography on silica gel, 2-hydroxy-oestriol-16,17-diacetate, m.p. 176–178°, was isolated. Alkaline hydrolysis, in the absence of oxygen, yielded 2-hydroxyoestriol, m.p. 267° (sealed, evacuated capillary tube), $\lambda_{\text{max}}^{\text{EtOH}}$ 289 m μ (ϵ , 3,656), $\lambda_{\text{min}}^{\text{EtOH}}$ 254.5 m μ (ϵ , 562), $[\alpha]_D^{19}$ + 44° (ethanol), $\nu_{\text{max}}^{\text{Nujol}}$ 3,420 and 3,190 (broad band), 1,600, 1,500 cm⁻¹.

All the above intermediates for which a melting point is quoted were obtained in the pure crystalline form and show satisfactory analytical figures. The yields were generally good, and these routes therefore

provide practical partial syntheses of these suspected metabolites from the available natural hormones.

The 2-hydroxyoestrogens are colourless, crystalline substances which dissolve freely in aqueous alkali, and may be recovered unchanged from their colourless solutions provided oxygen is excluded. In air or oxygen, rapid autooxidation occurs; approximately five atoms of oxygen per molecule of oestrogen are absorbed in a few minutes, with the production of an orange coloration, and the destruction of the aromatic A ring. Strong reducing properties are demonstrated by the ability of these compounds, as spots on paper, to give a blue coloration with the Folin-Ciocalteu reagent before exposure to ammonia vapour. The *R_F* values for paper chromatograms run with the system acetic acid (70)–water (30)–methylene-dichloride are: 2-hydroxyoestrone, 0.73; 2-hydroxy-oestradiol-17 β , 0.59; 2-hydroxyoestriol, 0.23 (oestradiol-17 β , 0.78; oestriol, 0.54).

Further work on the chemistry of these compounds is in progress, and the results of this, together with details of the syntheses outlined above, will be reported elsewhere.

Lysosomal-like Particles in the Rat Mammary Gland

DE DUVE *et al.*¹ have described the occurrence in rat liver of a new type of cytoplasmic particle, the lysosome, which was characterized by the following properties: (1) A distinct enzymic composition, containing a number of hydrolytic enzymes (acid phosphatase, β -glucuronidase, acid ribonuclease and acid deoxyribonuclease). (2) They can be isolated as a distinct intermediate fraction, between the mitochondria and microsomes, by differential centrifugation. (3) When isolated undamaged, the lysosomes show a low level of enzyme activity, but when the membrane is ruptured by freezing, and thawing, or by the addition of non-ionic detergents such as 'Triton-X-100', there is a considerable increase in the activity of the enzymes.

Recently, several other hydrolytic enzymes (aryl sulphatase, phosphoprotein phosphatase and β -glucosidases) have been reported to show properties similar to those outlined above (for references see ref. 1), and lysosomal-like particles have been reported to occur in a variety of tissues including rat brain, mouse liver, kidney and S.37 tumour².

We have investigated the possibility that similar particles exist in rat mammary gland by studying the effects of freezing and thawing and of 'Triton-X-100' on enzyme activation, and by comparing the sedimentation properties of these enzymes with mitochondrial and microsomal components.

The rats were adult females weighing about 200 gm. The litters of lactating mothers were restricted to 8-10 pups. Animals were killed by cervical dislocation, and the abdominal and upper inguinal glands were quickly dissected and placed into ice-cold aqueous 0.25 M sucrose. The tissue was homogenized in an Emanuel and Chaikoff homogenizer³. The tissue was first forced through the homogenizer using a clearance of 64 μ and the intractable connective tissue was removed by straining through cheese-cloth. The suspension was then finally forced through using the rod giving a clearance of 17 μ . The whole operation was done in a cold room at 4°. Enzyme assays on such suspensions were carried out as follows: cathepsin by the method of Greenbaum and Greenwood⁴ using haemoglobin as substrate; phosphoprotein phosphatase by the method of Paigen⁵; acid ribonuclease as described by Slater⁶; β -glucuronidase as outlined by Greenbaum and Greenwood⁴; acid deoxyribonuclease by the method of de Duve *et al.*⁷ and acid phosphatase by the method of Berthet and de Duve⁸. The activities found for both phosphoprotein phosphatase and acid phosphatase during lactation were very low and no activation studies could be performed with these enzymes. Mammary gland acid deoxyribonuclease, although showing activation on the addition of high final concentrations of 'Triton-X-100', appears to differ from that of liver in that it did not seem to be associated with particles in mammary suspensions; little of the activity could be sedimented by centrifuging for 16,000g for 20 min. Other work suggests that this enzyme is largely found in the milk retained in the ducts and alveoli of the gland⁹.

Cathepsin, acid ribonuclease and β -glucuronidase were, however, present in amounts suitable for activation studies. It was found that the activities of β -glucuronidase and acid ribonuclease were greatly increased by freezing and thawing the mammary suspensions or by the addition of 'Triton-X-100' as described by de Duve *et al.*¹⁰. Experimental results are shown in Fig. 1. Cathepsin, however, showed only a slight activation on the addition of 'Triton-X-100'. The activity in particle preparations from lactating

Fig. 1. Activation of acid ribonuclease (■), acid deoxyribonuclease (▲), cathepsin (●) and β -glucuronidase (○) by the addition of 'Triton-X-100' to the incubating medium. Enzyme activities are in arbitrary units and the procedures used for the assays are given in the text. All incubations were at 37° using mammary suspensions from rats in late lactation: the suspensions were prepared in 0.25 M sucrose using an Emanuel-Chaikoff type homogenizer³. The incubation times were 10 min. for acid ribonuclease and acid deoxyribonuclease, 20 min. for β -glucuronidase and 15 min. for cathepsin. The incubation medium was adjusted to a final concentration of 0.25 M sucrose with 1.7 M sucrose.

Fig. 2. Effect of increasing the time of homogenizing in a Potter-Elvehjem type homogenizer on the ratio of free/bound acid ribonuclease activity in rat mammary tissue suspensions taken from an animal in late lactation. The assay procedure for acid ribonuclease was as described by Slater⁶ and consisted of 1 ml. of ribonucleic acid in acetate buffer (0.1 M, pH 5.8, 4 mgm. ribonucleic acid per ml. buffer) + 0.2 ml. tissue suspension + 0.3 ml. 1.7 M sucrose. For total ribonuclease activity 0.1 ml. 1 per cent 'Triton-X-100' was added to the incubation mixture. The difference total activity minus free activity is the bound activity, that is, the activation produced by 'Triton-X-100'.

mammary gland suspensions was generally increased by about 30 per cent on the addition of 'Triton-X-100' in a final concentration of 0.2 per cent. This behaviour is analogous to the results of Beaufay and de Duve¹ on liver cathepsin.

When tissue suspensions of mammary gland in 0.25 M sucrose were centrifuged at 16,000g for 20 min. at 0° in an Angle 13 M.S.E. centrifuge, 70-80 per cent of the total activity of acid ribonuclease, β -glucuronidase and cathepsin was sedimented. On the other hand, if homogenization was carried out using a conventional Potter-Elvehjem type homogenizer with a plastic pestle (clearance 0.01 in.) for 2 min., more than 70 per cent of the total enzyme activity was in a non-sedimentable form and little activation by 'Triton-X-100' could be demonstrated. Thus it appears that homogenizing of mammary tissue with the Potter-Elvehjem technique causes damage to the particles containing these three enzymes; the damage caused was proportional to the time of homogenizing at 0° as shown in Fig. 2 for acid ribonuclease. Times of homogenizing up to 2 min. in the Potter-Elvehjem instrument, however, had no detectable influence on the sedimentation properties of mitochondrial enzymes cytochrome oxidase and succinate neotetrazolium reductase. Breakage of the particles containing cathepsin, β -glucuronidase and acid ribonuclease, with consequent lack of further activation by 'Triton-X-100', was also achieved by high-speed blending, and by incubating in hypotonic sucrose solutions.

It would appear that acid ribonuclease and β -glucuronidase behave similarly in mammary suspensions in response to osmotic activation, to freezing and thawing and to the addition of 'Triton-X-100'; on centrifuging in 0.25 M sucrose the two enzymes sediment in the same fraction as cathepsin. Their behaviour therefore closely parallels the properties reported by de Duve *et al.*⁷ for liver lysosomes. One point of great interest arising out of this work on mammary tissue suspensions concerns the variation in total enzyme activities over the lactation-cycle. Fig. 3 shows the variations in the total activities of cathepsin⁴, β -glucuronidase⁴ and acid ribonuclease⁶ as reported previously. It can be seen that these three enzymes, which show very similar properties with respect to activation and centrifuging, have very different patterns of change over the lactation-cycle. It would seem that if these three enzymes are located

Fig. 3. Variation in β -glucuronidase (■), acid ribonuclease (●) and cathepsin (▲) in rat mammary gland suspensions over the lactation cycle. Figures taken from the literature: for β -glucuronidase and cathepsin from Greenbaum and Greenwood⁴, for acid ribonuclease from Slater⁵.

within a similar type of lysosomal particle in rat mammary tissue, either independent variations in enzymic activities can occur at different physiological states or there is a variety of lysosomal particles each with specific enzymic constitutions. This latter possibility has been mentioned by Conchie and Levvy² and by Beaufay and de Duve¹.

It seems of interest to follow the ratio of bound/free lysosomal enzyme activity over the lactation cycle particularly in mammary involution where the tissue is degenerating rapidly. This is under investigation.

This work was done during the tenure of a Beit Memorial Fellowship held by one of us (T. F. S.) and of a Medical Research Council Studentship held by another (D. Y. W.).

Base Composition of Ribonucleic Acid from Rat Mammary Gland during Pregnancy and Late Lactation

ribonucleic acid has become increasingly associated with pathways of protein biosynthesis in many different types of tissue and there is a widely held belief that the sequential order of nucleotide bases in a particular ribonucleic acid molecule governs the amino-acid order of protein synthesized in its vicinity¹. Incorporation of amino-acid, which has been equated with protein synthesis under certain conditions, has been shown to occur under these conditions in the intracellular fractions from many tissues. Differences in the ribonucleic acid base composition of mitochon-

drial, microsomal and supernatant fractions have been found for rat liver^{2,3}.

The rat mammary gland undergoes a rapid change in physiological activity at parturition. The rate of protein synthesis increases rapidly, and concomitant with this there is a rapid increase in the gland's content of ribonucleic acid; this increase is largely centred in the particulate fractions of mammary suspensions⁴.

We have investigated the possibility that the sudden increase in both ribonucleic acid and protein synthesis occurring over parturition is accompanied by an alteration in the base composition of the newly synthesized ribonucleic acid. It was thought possible that the increase in the synthetic rate of the specific milk protein, casein, occurring over parturition might be sufficiently drastic to produce detectable alterations in the overall ribonucleic acid base composition. It was also of interest to study the base composition of lactating mammary gland ribonucleic acid to compare the acid-base composition of such an active protein secretory tissue with other tissues previously investigated.

The rats used were primiparous adult females the litters of which were restricted to 6-10 pups. All animals in the early pregnancy group were between 14-15 days pregnant; animals in the late-pregnancy groups were 17-20 days pregnant; the late-lactating groups were made up from animals 17-19 days lactating. Animals were killed by cervical dislocation and the abdominal and inguinal glands were quickly dissected and placed into ice-cold water. Tissue homogenates were prepared using a M.S.E. top-drive blender and the cold suspension strained through muslin to remove intractable connective tissue. For the experiments involving separations of intracellular fractions, homogenates were prepared in ice-cold 0.25 M sucrose using an Emanuel-Chaikoff homogenizer⁵; cell debris and nuclei were removed by preliminary centrifuging at 600g for 10 min. and the supernatant from this was then centrifuged at 105,000g for 20 min. at 0°. The sediment was resuspended in water to give the original concentration.

Ribonucleic acid was extracted from homogenates or tissue fractions essentially by the phenol method of Kirby⁶. The nucleotide base composition of ribonucleic acid samples was determined by the method of Herbert, Potter and Hecht⁷ using 'Dowex-1' resin in the formate form. The column size was 5 cm. $\times$ 0.72 cm.⁸; the rate of flow was approximately two 15 ml. fractions per hour.

The results for the base composition of mammary gland ribonucleic acid at three stages of the lactation-cycle are shown in Table 1. It can be seen that there is no significant alteration in the ratio of purine to pyrimidine bases at the three stages of the lactation-cycle studied. Thus, although the mammary gland changes very rapidly in protein synthetic ability during lactation, no significant alterations in the gross base composition of whole homogenate ribonucleic acid could be detected. Whereas in late pregnancy the protein synthetic machinery of the gland is concerned largely with the maintenance of the tissue protein itself, in lactation the emphasis is largely on the production of a very different protein, casein. Assuming that a close inter-relationship exists between ribonucleic acid and protein synthesis, it may be concluded that if differences in ribonucleic acid occur concomitant with a change over to the synthesis of a new protein, the differences are subtle and are not detectable by the type of overall base composition

Table 1. NUCLEOTIDE BASE COMPOSITION OF RIBONUCLEIC ACID SAMPLES EXTRACTED FROM MAMMARY GLAND TISSUE SUSPENSIONS AT THREE STAGES OF THE LACTATION CYCLE

The results are given as moles of nucleotide per 100 moles ribonucleic acid. A 12 per cent correction has been applied for the deamination of cytidylic to uridylic acid

determinations reported in Table 1 for whole homogenate ribonucleic acid.

The base composition of mammary gland ribonucleic acid appears to be somewhat different from the base composition of rat liver acid. Rat liver (and rat kidney) ribonucleic acid has been shown to have a purine/pyrimidine ratio of unity^{8,9}. Rat mammary gland acid, however, has a ratio of 1.34 but the ratio of 6-keto groups to 6-amino groups is 1.10 which is close to the corresponding value (1.08) given by Elson and Chargaff⁸ for rat liver ribonucleic acid. It would thus appear that rat mammary gland ribonucleic acid has approximately equal numbers of 6-keto and 6-amino groups but that the added regularity of a purine/pyrimidine ratio of unity is not present.

The results for the base composition of ribonucleic acid from intracellular fractions of rat mammary tissue taken from animals in late lactation are shown in Table 2. A major role in protein biosynthesis has been ascribed to the microsomal fraction of many tissues. However, it can be seen from Table 2 that in late lactation, when casein synthesis is at its peak, the particulate fraction of mammary tissue suspensions shows no significant differences in ribonucleic acid base composition from the soluble fraction remaining after approximately 3×10^6 g.min. There are indications that the nuclear fraction from mammary suspensions has a lower purine/pyrimidine ratio than the other fractions; a similar low ratio for liver nuclei has been previously reported⁴.

Table 2. BASE COMPOSITION OF RIBONUCLEIC ACID SAMPLES EXTRACTED FROM INTRACELLULAR FRACTIONS OF RAT MAMMARY GLAND SUSPENSIONS TAKEN FROM ANIMALS IN LATE LACTATION

For details of the centrifugings see the text. The results are expressed as percentages of the corresponding whole homogenate value for each base ratio (that is, the whole homogenate value for all ratios is 100)

Fraction	No. of experiments*	Molar ratios compared to whole homogenate value of 100				Purine/pyrimidine compared to whole homogenate value of 100
		AMP/OMP	UMP/OMP	GMP/OMP		
Nuclear	2	93	178	118		77
Particulates	4	100 ± 5	87 ± 5	97 ± 4		105 ± 3
Supernatant	6	116 ± 14	100 ± 7	106 ± 7		110 ± 8

* Two animals used per experiment

Total ribonucleic acid estimations were performed on the intracellular fractions, and the results were in agreement with earlier work on the distribution of ribonucleic acid in mammary tissue⁴. The bulk of the homogenate ribonucleic acid is associated with the particulate fraction (70–80 per cent); only some 10–20 per cent of the total suspension ribonucleic acid was found in the soluble fraction with the centrifuging procedure used. Thus the purine/pyrimidine ratio of the whole homogenate ribonucleic acid is largely determined by the purine/pyrimidine ratio of the particulate fraction. This is shown in Table 2, where it can be seen that the purine/pyrimidine ratio for the particulate fraction is not statistically different from the whole homogenate value.

Ribonuclease did not have any appreciable effect on the bulk of the ribonucleic acid since in experiments where homogenates were allowed to stand for 2 hr. at 0° no differences in the purine/pyrimidine ratios were observed compared with similar homogenates placed in phenol immediately after homogenization (2 hr. was approximately the time taken to prepare the intracellular fractions before phenol extraction). It has been shown that ribonuclease is associated with lysosomal-like particles in rat mammary tissue¹⁰ and that when a mammary suspension is prepared using an Emanuel-Chaikoff type homogenizer, only some 10 per cent of the total ribonuclease is in a free and non-sedimentable form.

It would thus appear from the results obtained in this investigation that there is no gross alteration in the base composition of mammary gland ribonucleic acid at the three stages of the lactation-cycle studied. Further, during late lactation, there are only small differences between the base compositions of ribonucleic acid extracted from intracellular fractions. Since the differences in composition of ribonucleic acid, which almost certainly occur in the mammary gland in response to the stress of lactation, cannot be detected by overall base composition analyses a study has been initiated on the composition of ribonucleic acid species isolated by chromatographic techniques similar to those used in the studies of Goldthwaite¹¹ on liver.

Binding of Zinc in Carboxypeptidase

CARBOXYPEPTIDASE is a metallo-enzyme which contains zinc. It has been reported by Coleman and Vallee¹ that the enzyme can be de-activated by removal of zinc and that activity can be restored by the addition of zinc, cobaltous, ferrous, nickel and manganous ions but not by addition of cadmium, magnesium or calcium ions. This metallo-enzyme therefore falls in the group of enzymes which have no specific metal requirement for activity². In biological systems, however, a particular metal, zinc, is associated with the enzyme presumably because complex ion equilibria favour this particular association over all others. The situation is not very different from that found in the case of the enzyme enolase, where magnesium and manganous are the particular ions associated with activity in the biological system, but where other cations such as zinc can activate the enzyme *in vitro*³. The apparent stability constants for the association of zinc and cobaltous ions with carboxypeptidase are 2×10^8 and 1×10^6 respectively¹. The pH range of activation by the different cations indicates that association with the active centre is in the order zinc(II) > nickel(II) and cobalt(II). The study of complexes of a wide variety of simple organic ligands has shown⁴ that this stability sequence is observed only when one of the co-ordinating centres is sulphide, R-S-. I conclude that zinc is bound by a sulphide group in carboxypeptidase and give the following additional evidence in support of this binding.

The cobaltous carboxypeptidase complex is highly coloured. The molar extinction coefficient at 530 m μ is 150¹. The usual value of the extinction coefficient of cobaltous complexes is <10, except when the cobalt ion is bound to large, polarizable ligand atoms such as chloride and sulphide⁴. Thus both cobaltous thiocyanate and thiosulphate have extinction coefficients of the order of 10³, and cobaltous cysteine and thioglycollate complexes are highly coloured. In the complex with carboxypeptidase, the binding of the cobaltous ion is probably restricted to oxygen, nitrogen or sulphur centres, and it would appear that only in the case of binding to sulphur is the colour of the complex explicable from the known properties of model complexes. The shift of the absorption band from 512 m μ in the hydrate to 530 m μ in the carboxypeptidase complex, that is, a shift to longer wavelengths, is in the expected direction if binding to cobalt is through a mixture of oxygen and sulphur co-ordinating centres, but is in the opposite sense from the shift produced by extensive co-ordination to nitrogen.

In the metallo-enzyme enolase I have postulated that the binding of the cations is largely through oxygen atoms². In this enzyme magnesium is active. Magnesium cannot activate carboxypeptidase. It is not known to bind to sulphide groups. On the other hand, cations such as lead(II), cadmium, mercuric, silver, and cupric which bind sulphur groups more strongly than zinc may be expected to be powerful inhibitors.

If cobalt is bound to sulphur in carboxypeptidase, it is possible to predict that there will be a further new absorption band absent in the complexes of the other cation complexes of this enzyme. The new band will be at about 285–300 m μ and will have an extinction coefficient greater than 10³. Both this strong band and the band in the visible of extinction coefficient 10³ are present in model cobalt complexes containing Co—S—R links⁴. Neither of these bands

is observed in cobaltous insulin, and we can predict that in this complex the binding of zinc is to a mixture of oxygen and nitrogen groups. Both insulin and carboxypeptidase contain sulphur groups.

Note added in proof. Since this communication was submitted I have heard from B. L. Vallee and his associates that they have demonstrated Zn—S binding independently.

A Plate Assay for Elastase

SINCE Balo and Banga¹ described the pancreatic enzyme elastase, its dissolving effect on elastin, and its possible implications in atherosclerosis, a considerable amount of interest has been focused on the quantitative measurement of its enzymatic activity.

Two methods most commonly used for the assay of elastase are based on gravimetric measurements and nephelometry. Much has been learned in regard to the interaction of elastin and elastase and its inhibitor, serum, by these two methods. However, both methods suffer from the fact that they require much time and special equipment and skilled personnel.

If a programme designed to establish and follow elastase-inhibitor levels in sera from a variety of sources, including human sera, is anticipated, a relatively easy and rapid assay for elastase and its inhibitor is essential. Such a programme is in progress in this laboratory, and an assay fulfilling these requirements has been developed.

Table 1. WATER-SODIUM HYDROXIDE ELASTIN IS USED. IT IS AUTOCLAVED FOR 10 MIN. AT 10 LB. PRESSURE. THE RESULTING pH IS 7

Components	Composition of elastin medium Amount of components in stock solution	Volume of stock solutions for 100 ml. of complete medium
Inorganic salts		
K ₂ HPO ₄	25 gm.	
KH ₂ PO ₄	25 gm.	
Distilled water	250 ml.	0.5 ml.
Inorganic salts B		
MgSO ₄ · 7H ₂ O	10 gm.	
NaCl, FeSO ₄ · 7H ₂ O	0.5 gm.	
MnSO ₄ · 4H ₂ O	of each	
Distilled water	250 ml.	0.5 ml.
Elastin	10 gm.	
Distilled water	100 ml.	10 ml.
Distilled water		87.5 ml.
Agar		1.5 gm.

Table 1 shows the composition of elastin agar. 20 ml. of this medium is poured into a sterile 15 × 150 mm. Petri dish. The non-transparent medium (due to the presence of elastin) is allowed to harden. Six wells are made in the medium by either allowing the medium to harden in the presence of plastic molds which can then be easily removed after hardening, or the medium is allowed to harden and the molds are pushed through the agar. The resulting cylinder of agar can be teased away with an inoculating needle. The wells serve as reservoirs for elastase and its inhibitor serum. The diffusion of elastase from the wells and its subsequent dissolution of elastin result in clear zones around the wells, the zones varying in diameter with the concentration of elastase used. The resulting clear zones can be seen

Fig. 1. Photograph of an elastin agar plate showing solubilization (clear zone) of elastin around the wells containing decreasing concentration of elastase, wells A-E (5, 4, 3, 1, 0.5 mgm.); F is a buffer control. 0.06 ml. of bovine pancreatic elastase in the desired concentration is placed in each well. An equal amount of buffer (not containing elastin) is placed in well F. The plates are allowed to incubate right side up for 72 hr. at room temperature. The zone of solubilization can be read at each 24-hr. interval. Bovine pancreatic elastase was prepared according to the method of Lewis (ref. 3). Water-sodium hydroxide elastin was prepared by the method described by Gilfillan *et al.* (ref. 4).

in Fig. 1. Inhibition of elastase can be easily demonstrated by the addition of serum to the reaction well. The results obtained when a constant amount of elastase is placed in each of five different wells along with decreasing concentrations of serum are illustrated in Fig. 2. The inhibitory effect of serum is obvious. Partridge and Davis² have shown that elastin degradation is accompanied by the liberation of N-terminal substances. Ninhydrin added to the well surrounded by the clear area shows a bluish-purple area indicating the liberation of free amino groups.

Preliminary work indicates that this plate assay correlates well with the nephelometric-ninhydrin method used by Gilfillan *et al.*⁴

We believe that the elastase plate assay described is less time-consuming, requires less special equipment, does not require skilled personnel, and most important is readily adaptable to assaying large numbers of sera for elastase inhibitor or tissue, bacterial, and fungal extracts for elastase.

Fig. 2. Photograph of an elastin agar plate showing the inhibitory effect of third trimester pregnancy serum on elastase. The elastase concentration (5 mgm./well) was constant in wells A-E. Serum concentrations decreased from A to E (1/20, 1/40, 1/60, 1/80, 1/160). Well F contained an equal amount of serum and served as a control. Plates are incubated and read as in Fig. 1. (Photographs taken by George Daynes)

PHYSIOLOGY

Specific Activities of Acid-soluble Nucleotides in Hind-Leg Muscles of Mice with Dystrophia Muscularis

In an earlier paper¹, we showed that the concentrations of adenosine monophosphate, guanosine triphosphate and guanosine diphosphate were significantly higher in the hind limb muscles of dystrophic mice than those obtained for normal mouse muscles, while for adenosine triphosphate the reverse was found. Although the concentration of the adenosine diphosphate component was the same for both normal and dystrophic tissue, radioautographs of nucleotides containing radioactive phosphorus seemed to show an area of higher radioactivity for the adenosine diphosphate derived from the dystrophic muscle. The present work was designed to examine the turn-over rates of the acid-soluble nucleotides in the skeletal muscle of normal mice and mice afflicted with a hereditary myopathy (dystrophia muscularis).

Both dystrophic mice and their normal litter mates (obtained from the Roscoe B. Jackson Memorial Laboratories, Maine) were injected subcutaneously with carrier-free radioactive phosphorus (20 μ c./gm. body-weight). Two hours later, the animals were anesthetized and the hind leg musculature was excised. In order to minimize the enzymatic degradation of the nucleotides, the muscle was handled at temperatures of 0° C. or below¹.

After weighing the frozen tissue on a torsion balance, the muscle was transferred to a homogenizing flask containing 10 ml. of 0.25 M perchloric acid (1-2° C.) per gm. of tissue². 0.5-1.0 gm. of muscle tissue was available for each analysis. The sample was homogenized for 10-20 sec. at 40,000 r.p.m. and then centrifuged (3,000 r.p.m.) for 15 min. at 0° C. A 10 per cent suspension of acid-washed 'Norite' (0.4 ml./gm. of extracted muscle tissue) was added to the supernatant and the emulsion was agitated for 30 min. in the cold³⁻⁵. The 'Norite' was separated by centrifugation, washed with water and recentrifuged. 10 per cent pyridine in 60 per cent ethanol (8 ml./gm. extracted muscle tissue) was added to the 'Norite'. The contents of the tubes were mixed, and elution was allowed to proceed over a 2-hr. period at 37° C. with occasional mixing⁵. The charcoal was removed by centrifugation, and the eluate containing the acid-soluble nucleotides was measured. Aliquots were taken for the measurement of radioactivity present in the total extracted nucleotides, and the remaining eluate was concentrated to a small volume.

The concentrated nucleotides were quantitatively transferred to Whatman No. 1 filter paper and re-

* Specific activity = $\frac{\text{counts per min.}}{\mu\text{mol. of nucleotide (average of 18 determinations)}}$

† Animals killed 2 hr. after the subcutaneous injection of radioactive phosphorus.

‡ Guanosine tri- and di-phosphate contain other nucleotides (ref. 1).

solved by descending chromatography for 40 hr. using the isobutyric acid-ammonium isobutyrate solvent system of Magasanik⁶. Following resolution of the unknown mixture, 6 spots corresponding to adenosine monophosphate, diphosphopyridine nucleotide, adenosine diphosphate, adenosine triphosphate, guanosine di- and tri-phosphate were made visible with ultra-violet light. However, radioautographs prepared from the chromatogram indicated the presence of an unidentified radioactive phosphorus-containing substance in the adenosine monophosphate-diphosphopyridine nucleotide area, which did not absorb ultra-violet light. Since we were interested in the specific activity of each component, and this non-nucleotide substance might contribute to the specific activity of either adenosine monophosphate or diphosphopyridine nucleotide, it was necessary to remove this compound before eluting the adenosine monophosphate and diphosphopyridine nucleotide. This was accomplished by ascending chromatography in the second dimension for 5 hr. at 20° C. using the *n*-butanol/*n*-propanol/formic acid (10:40:30) solvent of Venkstern and Baev⁷. With this solvent, the unidentified component as well as orthophosphate were resolved away from the nucleotides, which remained at the origin.

Quantitative elution and estimation techniques for the separated nucleotides were the same as described in the previous publication¹. After determining the optical densities of the various eluates, aliquots were pipetted into metal planchets. The counting samples were dried and radioactivity measurements were determined with a Nuclear Chicago gas-flow counter.

The specific activities calculated for the acid-soluble nucleotides obtained from the hind-leg musculature of 5 dystrophic and 4 normal mice run by the above procedure are tabulated in Table 1. Significantly higher specific activities were found for the adenosine diphosphate (226,700), diphosphopyridine nucleotide (24,500), and guanosine diphosphate (478,600), from the dystrophic mouse muscle, as compared to normal values of 149,400 for adenosine diphosphate, 12,100 for diphosphopyridine nucleotide, and 310,000 for guanosine diphosphate. On the other hand, little or no differences existed in the specific activities of the adenosine mono- and tri-phosphate, and guanosine triphosphate derived from the two types of tissue.

Although the concentration of adenosine triphosphate from the dystrophic tissue is 30–40 per cent lower than that found in normal tissue, the specific activities for adenosine triphosphate from both types of tissue are not significantly different. While it has been postulated that adenosine triphosphate plays a significant part in all phases of muscle metabolism, the roles of the other acid-soluble nucleotides cannot be

dismissed⁸. In view of the significantly higher specific activities of adenosine diphosphate, guanosine diphosphate and diphosphopyridine nucleotide, it is possible that they contribute through secondary pathways to make up for the deficiency in adenosine triphosphate.

A more comprehensive study of the turn-over rates of the various acid-soluble nucleotides is in progress.

We wish to express our gratitude to Dr. Solomon A. Berson and to Dr. Stanley M. Aronson for their helpful advice throughout the course of this work.

Storage and Release of Catecholamines, and the Occurrence of a Specific Submicroscopic Granulation in Hearts of Cyclostomes

THE relatively large amounts of catecholamines found in the hearts of cyclostomes^{1,2} suggest that these substances may be stored in specific cells or cellular structures. Preliminary examination with the light microscope of specimens from the hearts of the lamprey (*Petromyzon fluviatilis*) and the hagfish (*Myxine glutinosa*) indicated the presence of a specific cell type possibly serving as store. It was therefore considered of interest to analyse different cardiac structures of these two cyclostomes with regard to their content of catecholamines and to make a parallel study of the morphology of this unknown cell with the aid of the electron microscope.

Adrenaline and noradrenaline were determined fluorimetrically by the method of Euler and Lishajko³ after extraction of the hearts with 5 per cent trichloroacetic acid, adsorption on alumina and elution

with acetic acid. Column chromatography of an eluate obtained with sulphuric acid was used for the determination of catechol compounds in general. A granular fraction was also isolated by high-speed centrifugation of press juice from the hearts according to the method described by Euler⁴, using 0.3 M and 0.075 M potassium phosphate as medium for *Myxine* and *Petromyzon* hearts, respectively.

For histological examination specimens were freeze-dried or fixed in various fixatives and were studied under light and fluorescence microscopes. For electron microscopy specimens were fixed in buffered osmic acid and embedded in methacrylate; sections were examined in an R.C.A. type EMU 2 B electron microscope.

Table 1. ADRENALINE (A) AND NORADRENALINE (NA) IN HEARTS OF *Petromyzon fluviatilis* (LAMPREY) AND *Myxine glutinosa* (HAGFISH) IN μG PER GM.

	Auricle		Ventricle		Portal heart	
	A	NA	A	NA	A	NA
Lamprey	140	3.4	25	0	—	—
	118	7.6	24	0	—	—
	132	7.9	35	0	—	—
Hagfish	15	40	40	5.6	3.1	53
	11	54	49	6.4	0.3	59
	—	—	—	—	4.5	44

Table 1 shows the amounts of adrenaline and noradrenaline in the auricle and the ventricle of lamprey and hagfish and also in the portal heart of hagfish. It can be seen that the lamprey heart contains chiefly adrenaline which is present in large amounts in the auricle as well as in the ventricles. In the hagfish a peculiar distribution of the two amines is noted in that the portal heart and the auricle contain mainly noradrenaline, while adrenaline is the dominating amine in the ventricle.

By column chromatography of heart extracts of hagfish and lamprey it could be shown that adrenaline and noradrenaline were the predominant catechol compounds and that dopamine and dihydroxyphenylacetic acid were present only in very small amounts. In fractions of isolated granules the proportion of the two amines was approximately the same as that found in total extracts.

It has recently been shown that reserpine causes a release of noradrenaline from isolated transmitter granules from mammalian splenic nerves⁵. Incubation of isolated granules from *Petromyzon* and *Myxine* hearts with reserpine (0.1 mgm./ml. for 30 min. at 20° C. and pH 6.1) increased the release of catecholamines from the granules by about 30 per cent as compared with the controls.

After 6 daily injections of 0.1–0.2 mgm. reserpine subcutaneously the amounts of adrenaline and nor-

adrenaline in the hearts of *Myxine* and *Petromyzon* were reduced to 15–30 per cent of the control values.

Electron micrographs of specimens of hearts from both species have revealed the occurrence of numerous cells containing large numbers of dense, osmiophilic granules, round in shape and measuring in diameter about 0.1 μ . The granules generally show a distinct border surrounded by a lighter space which in turn is encircled by a limiting membranous structure (Fig. 1). With regard to the localization of these granules, this varies in a somewhat puzzling way. In the hagfish auricle, accumulations of granules have been observed in what appears to be ordinary heart muscle cells. However, in both species there appear to be present specific cells, extremely rich in granules of the type described. Hitherto two types of such cells have been observed, one characterized by a dark-staining cytoplasm which is completely packed with granules, and the other showing a light, almost empty-looking cytoplasm with only few granules. It is at present not possible to state if two different cell types really exist or if the varying appearance may be due to different functional stages of one and the same cell type.

The granular structures found in the hearts of these two fish species show a striking morphological resemblance to the granules found in cells of the adrenal medulla of the rat⁶ and of the mouse, guinea pig and cat⁷. Furthermore, the varying appearance of the cells is very similar to that described by Lever⁶ in adrenal medullary cells of the rat. He describes: "a dark cell in which abundant osmiophilic adrenaline granules are contained in a relatively opaque background cytoplasm and a light cell containing fewer secretory granules".

It is at present not possible to draw definite conclusions as to the true nature of the granular cells encountered in hearts of the cyclostomes *Myxine* and *Petromyzon*. However, taking into consideration the large amounts of catecholamines present in heart tissues of these fishes and the interesting observation that characteristic nervous elements seem to be lacking in *Myxine*² it seems possible that we are here dealing with a cell type belonging to the chromaffin system.

This investigation is being continued, and a full report will be presented elsewhere.

Cannulation of Minute Mesenteric Veins for Continuous Portal Perfusion of Rats

THE introduction of a cannula into a very small vein (< 1 mm.) is almost impossible because of collapse and cohesion of the vessel walls. Any looping or clamping of the vein beyond the incision in order to avoid bleeding and to maintain a clear visual field causes spasm which will not permit further passage of the tubing into the vascular lumen. If the cannula is forced, it will perforate the thin vessel. We have, therefore, constructed a cannulating device which permits the introduction of a fine plastic tubing into a small vessel without visual control.

Fig. 1

The device consists of a No. 22 injection needle, 1½ in. long, the distal ½ in. of which is bent to a right angle so as to form a trough terminating at the needle point. To this trough, and just at the base of the needle point, is soldered a straight 1 in. long metal cannula, which forms an angle of about 15° with the base of the needle trough (Fig. 1). A polyethylene tubing (No. 10 Clay-Adams) with a square end is introduced into the metal cannula which will guide the plastic tubing exactly to where the point of the angled needle has punctured the vessel. When the plastic tubing is now pushed forward, it passes close to and beneath the needle point into the vascular lumen (Fig. 1). In spite of lack of visibility due to the bleeding from the punctured vessel, successful cannulation is evident from the flow of blood into the tubing. Threads which have been previously passed under the vessel and looped are tied after the point of the cannulating device has been pulled back about 3 mm. The plastic cannula is now firmly grasped with a thumb forceps in front of the needle point and held in position while the cannulating device is slipped off the tubing. The polyethylene tubing is filled with a 1:10,000 heparin-saline solution and stoppered. Eighty-eight female rats weighing 220–260 gm. were anaesthetized with intraperitoneal 'Nembutal' (6 mgm./100 gm. body-weight) and a laparotomy with exposure of the ileocaecum was carried out. The ileocaecal loop and its mesentery containing the exposed vein were spread on a thin cork plate covered with moist gauze. The mesentery was pinned down to the cork plate in order to permit the smooth sliding of the cannula into the stretched vein. The cannulating device containing the plastic tubing was attached to the barrel of a 2 c.c. syringe, thus providing a steady grip of the instrument. The cannulation of the ileocaecal vein by this technique is done close to the intestinal border of the mesentery. The abdomen is closed in two layers and the cannula brought out through the most cephalad part of the mid-line incision

to prevent the rats from catching their hind-feet in the cannula. A small glass bead is slipped over and glued to the cannula at its point of exit from the abdominal wall. The cannula is fixed by putting a suture through the skin and tying it in front of the glass bead. The animals are then restrained¹ and continuously perfused with various solutions.

Of the 88 rats, 26 have been perfused for less than 3 days, 41 have been perfused for 4–10 days, and 21 have been perfused for more than 10 days.

ANATOMY

Histochemical Demonstration of Aromatic Monoamine in the Locus Cœruleus of the Mammalian Brain

SHIMIZU *et al.* have reported several interesting histochemical results of the locus cœruleus of the mammalian brain—the strong activity of acid phosphatase¹ and cholinesterase² but rather poor action of respiratory enzymes^{3,4}, and further, characteristically strong monoamine oxidase activity⁵. The last finding led us to suppose that some aromatic monoamines such as catechol amines and serotonin would be concentrated in the locus. Although Falck and Hillarp⁶ recently reported that no chromaffin reaction could be observed in the hypothalamus and the caudate nucleus, and concluded that noradrenalin and dopamine are not stored in a small number of nerve cells of these regions, they did not examine the locus cœruleus. In the present investigation several histochemical reactions including argentaffin, Schmorl's, chromaffin, azo-coupling and Gibbs's reaction were carried out in mammalian brain tissues containing the locus cœruleus.

The materials used were taken from the healthy adult rabbit, rat, mouse, guinea pig, dog and cat and also from the scorbutic guinea pig and animals treated with marsilid or catron. All tissue slices were fixed in 10 per cent neutral formalin or 5 per cent potassium bichromate-chromate solution with or without formalin⁷. The specimens were quickly embedded in paraffin, since a yellow compound due to an oxidation of chromaffin substances might be dissolved in hot paraffin⁸. The sections (7–10μ) were subjected to the following histochemical reactions: the argentaffin reaction (Gomori's methenamine silver or Fontana's ammoniacal silver solution, cf. Pearse⁹) for 24 hr. without pretreatment with Gram's iodine solution, Schmorl's ferricyanide reaction (Lillie and Burtner¹⁰), azo-coupling reaction (diazo blue B in alkaline solution, cf. Pearse⁹) and Gibbs's reaction (cf. Gomori¹¹). The results are summarized in Table 1.

The silver or Prussian blue granules due to the presence of a reducing substance occurred almost exclusively in the locus cœruleus of all animals hitherto studied except for rats and mice, where the

—, No reaction; ±, slightly positive reaction; +, weak reaction; ++, moderate reaction.

granules were always recognized within the nerve cell bodies and their processes but not in the neurophil. It should be mentioned, however, that the granules did not occur equally in all specimens tested, and they were not always demonstrated in all nerve cell bodies of the nucleus, but their quantity and distribution varied according to the animal species used. The granules, for example, were observed most abundantly in the dog, cat and guinea pig (Fig. 1a) but slightly in the rabbit and were absent in the rat and mouse. Similar but less amounts of these granules were further revealed in the dorsal nucleus of the raphe of the rabbit, dog and cat. These granules positive for argentaffin or Schmorl's reaction were further tested with chromaffin, Gibbs's and azo-coupling reactions. Although the former two were negative, the last gave slightly positive reaction.

This substance was still capable of reducing ammoniacal silver or ferricyanide after the sections had been exposed to some of the blocking agents for SH groups and aldehydes. Shimizu *et al.*¹² recently showed histochemically the characteristic deposition of ascorbic acid in the locus cœruleus, which completely disappeared in the scorbutic guinea pigs. These granules were demonstrated with the argentaffin and Schmorl's reactions even in the scorbutic guinea pig's brain. These results seem to indicate that the reducing capacity of the granules is not ascribed to the presence of SH, aldehyde and ascorbic acid.

Furthermore, administration of a specific inhibitor of monoamine oxidase (1-phenyl-2-hydrazinopropane, catron, JB-516), 200 mgm./kgm., to normal rats, in which the granules could not be demonstrated, produced the appearance of abundant reducing

granules in the locus cœruleus (Fig. 1b). This experiment indicates that this reducing substance might be the physiological substrate of monoamine oxidase in this locus.

The present observations, together with the previous result of the pronounced monoamine oxidase activity in the locus⁵, suggest that the reducing granules occurring in the locus cœruleus might consist of aromatic monoamine. It is likely that they could not be demonstrated by the chromaffin and Gibbs's reactions, because they occurred in low concentration and were scarcely recognizable.

The possibility that the locus cœruleus probably contains aromatic monoamine might also be supported by the recent physiological investigation by Megawa¹³, which showed that the electrical stimulation of the locus has displayed the characteristic parasympathetic reactions. Brodie and Shore¹⁴ suggested that serotonin acted as the chemical transmitter of the central parasympathetic system. This substance in the locus cœruleus seems to be easily demonstrable with fixation of formaldehyde and its reducing capacity seems to be weakened or abolished after fixation without formalin, a fact which resembles the enterochromaffin substance, serotonin. From our histochemical results and the physiological data of other investigators^{13,14} it may be supposed that the locus cœruleus contains aromatic monoamine acting as parasympathetic transmitter.

RADIOBIOLOGY

Reaction of Formaldehyde with Deoxyribonucleic Acid in Phage T1

In viruses the formaldehyde reaction takes place not only with the protein but also with the ribonucleic acid, as has been shown by Fraenkel-Conrat¹. According to Staehelin² the binding of formaldehyde by ribonucleic acid appears to be a specific function of the amino-groups of the bases. Yet there is no formaldehyde reaction with amino-groups involved in hydrogen bondings, as is the case in the double-stranded deoxyribonucleic acid³. If this acid is subjected to dialysis with distilled water for several days in the cold (a procedure which is believed to break hydrogen bonds) it is rendered more reactive

b, Locus cœruleus of the catron-administered rat. Showing the appearance of abundant granules. The animal was killed 4 hr. after subcutaneous administration of catron (200 mgm./kgm.). Fixation with formalin. Gomori's methenamine silver reaction. ($\times c. 450$)

towards formaldehyde². This increased reactivity is reversible by addition of a buffer².

In concentrations lower than 1 per cent, formaldehyde is supposed to react with nucleic acid by forming monomethylol groups ($-\text{NH}-\text{CH}_2\text{OH}$), which can afterwards form methylene bridges by condensation². The formaldehyde reactions in proteins have been discussed by Fraenkel-Conrat³. Heicken and Spicher⁴ studied the inactivation and reactivation phenomena in phage T1 after formaldehyde treatment. Since amino-methylol groups are unstable², inactivated phages can be reactivated by storage in the presence of formaldehyde-binding media⁴. The reactivation-rate is low and does not disturb inactivation experiments if constant conditions for phage growth are used.

The following experiments were performed to decide whether the formaldehyde inactivation of T1 is caused by protein damage or by reaction with the deoxyribonucleic acid.

It is known that the ultra-violet survival curve of T1 is made up of two components of different ultra-violet sensitivities, where the lower sensitivity results from a reactivation of a certain fraction of inactivated phages, probably by the genome of the host bacterium^{5,6}. This host cell reactivation requires an injection of the phage genome and can therefore be used to indicate that an inactivated phage still injects its deoxyribonucleic acid. It is further known that doses of ultra-violet light commonly used for inactivation experiments do not affect the adsorption and injection mechanisms of bacteriophages to an appreciable extent. If other inactivating agents permit a host cell reactivation at least involving the same number of inactivated phages as does ultra-violet light, it may be concluded that the inactivation results from damage in the phage genome and that the adsorption and injection mechanisms are not disturbed to any greater extent than after ultra-violet irradiation. If T1 is inactivated by a solution of formaldehyde in distilled water (pH 5.6), the survival follows an exponential function of the formaldehyde dose (Fig. 1, curve A). But if T1, inactivated under the same conditions, is pre-adsorbed on bacteria irradiated with ultra-violet light (*E. coli* B), the number of plaque-forming T1 is markedly decreased, since the reactivating mechanism within the bacteria is destroyed by the irradiation (Fig. 1, curve B); whereas the capacity of irradiated cells to yield progeny from untreated T1 is unchanged. This indicates that a great number of inactivated phages are reactivated by the host bacterium and that the formaldehyde reaction takes place in the genome. A comparison was made between the sensitivity of T1 towards formaldehyde and ultra-violet light, when in both cases the phage is propagated in bacteria irradiated with ultra-violet light, and the sensitivity towards formaldehyde and ultra-violet light when phages are grown in bacteria that perform a reactivation. After ultra-violet irradiation as well as after inactivation by formaldehyde, and within the experimental error, the ratio of total hits to those that cannot be reactivated is about 7:2 (Fig. 1, curves B and C). The similarity of the ratios makes it probable that the inactivation occurs in the same structure in the case of ultra-violet and formaldehyde treatment. As the reactivation is believed to be a result of recombination between homologous parts of phage and bacterial genome, equal ratios would be expected, if the protein damage after treatment with formaldehyde is negligible.

Fig. 1. Survival of formaldehyde-inactivated T1 in normal and ultra-violet irradiated *E. coli* B. Curve A, survival after pre-adsorption to unirradiated bacteria. Curve B, after pre-adsorption to bacteria irradiated by ultra-violet light, 180 sec. (a dose reducing the colony-forming ability of *E. coli* B by a factor of 10^4). Broken lines, decline and size of the two components of the survival curve B; ratio of declines 3:2:1. Curve C, dotted lines, decline and size of the two components of the T1-surviving curve after ultra-violet irradiation and propagation in untreated *E. coli* B; ratio of declines 3:5:1. Abscissa, time of incubation with formaldehyde and of ultra-violet irradiation respectively. Ordinate, relative number of surviving T1.

But there exists still another possible explanation for the results in curve A and curve B of Fig. 1. In the case of inactivation by formaldehyde each phage which is injected survives by reactivation independently of the number of formaldehyde hits in its genome. Then, the inactivation measured in curve A must prevent the injection of the genome. By ultra-violet irradiation of the host bacteria, the ability for phage reactivation is lost in a certain number of cells and the damage by formaldehyde can be expressed (curve B). The ratio 3:2:1 would give the sensitivity of the total phage to the sensitivity of absorption and injection mechanisms. This explanation is very improbable, as it demands a survival of each injected phage independently of the number of formaldehyde hits in its genome.

According to the results of Fig. 1, formaldehyde hits and ultra-violet hits show the same relations concerning inactivation and host cell reactivation. Therefore, after inactivation by formaldehyde of T1 to 10 per cent or less survivors, the ultra-violet-surviving curve of the phages after subsequent irradiation should be an exponential function of the ultra-violet dose with the same slope as that of the 30 per cent fraction in the ultra-violet curve of untreated T1 (Fig. 2, curves A, B and C). (The steeper decline of the curves B, C and D in Fig. 2 is caused by the formaldehyde which has been present during irradiation in different concentrations⁷.) Inactivation by formaldehyde to about 60 per cent survivors must yield an ultra-violet curve at subse-

Fig. 2. Ultra-violet survival curves of T1 after preceding treatment with formaldehyde. Curve A, dotted line, ultra-violet survival curve of normal T1. Curve B, inactivation by formaldehyde to 65 per cent survivors and subsequent ultra-violet irradiation. Curves C and D, inactivation by formaldehyde to 9 per cent, respectively, 0.7 per cent survivors and subsequent ultra-violet irradiation. (The steeper decline of curves C and D results from an increased reaction-rate of formaldehyde with ultra-violet irradiated T1, ref. 7.) Curve E gives the survival of T1 after incubation with a 0.1 per cent formaldehyde solution in distilled water (pH 5.6) at 37°C. Abscissa, time of ultra-violet irradiation (for curves B, C and D the scale begins with the first point on the formaldehyde-inactivation curve); and time of treatment with formaldehyde respectively. Ordinate, relative number of surviving T1

quent irradiation, which is still composed of two fractions of different ultra-violet sensitivities (Fig. 2, curve B).

The results in Figs. 1 and 2 indicate that the inactivation of T1 by formaldehyde is mainly caused by a reaction with the phage genome. The fact that the ratio of reactivable to non-reactivable hits is the same in the case of formaldehyde and ultra-violet inactivation makes a formaldehyde reaction with the deoxyribonucleic acid most probable. The reaction has to occur with free amino-groups, which shows that not all possible hydrogen bonds are established in the deoxyribonucleic acid of T1.

Effects of Ultra-Violet Light on Hydrogen Bonds in Deoxyribonucleic Acid of Phage T1

PHAGE T1, inactivated by formaldehyde, still injects its deoxyribonucleic acid, as can be shown by the degree of reactivation of 'formaldehyde-hits'. The formaldehyde inactivation of T1 is believed to result from a reaction with the amino-groups of the bases in the deoxyribonucleic acid¹. As Staehelin² has shown, formaldehyde in concentrations lower than 1 per cent reacts with free amino-groups of nucleic acids, but it does not react if these groups are involved in hydrogen bondings. Furthermore, the experiments of Nitschmann and Hadorn³ make a formaldehyde reaction with the free imino-groups of the bases improbable.

Ultra-violet irradiation might cause a break of purine-pyrimidine hydrogen bonds in deoxyribonucleic acid. This break could be a non-lethal effect either in that it is reversible or in that it does not influence the viability of the phage. If ultra-violet light breaks hydrogen bonds in deoxyribonucleic acid, this would lead to an increased reaction-rate of formaldehyde with the amino-groups of the nucleic acid; but there should be no increase in phages with single stranded nucleic acid, if the reaction with the protein is not increased after ultra-violet irradiation. Presuming that a break of a hydrogen bond in the deoxyribonucleic acid is not necessarily lethal, the increased reaction-rate of formaldehyde with ultra-violet-irradiated phage deoxyribonucleic acid must lead to an increased inactivation-rate of irradiated

Fig. 1. Survival of T1 after irradiation with ultra-violet light. Dotted line, untreated T1, fraction which performs host-cell reactivation. Curve A, survival of T1 after pretreatment with formaldehyde and subsequent irradiation in buffer. Curve B, survival after irradiation in a 0.9 per cent formaldehyde solution in buffer. The steeper decline in the curve B does not result from an increased ultra-violet sensitivity, but shows the increased reaction-rate of T1 with formaldehyde after irradiation. Abscissa, time of irradiation; ordinate, relative number of surviving T1

T1 by formaldehyde; and this increased inactivation-rate can easily be measured.

As a restitution of the hydrogen bonds might occur immediately after the break by ultra-violet light, the incubation with formaldehyde was performed during irradiation. In a first set of experiments, T1 was irradiated by ultra-violet light of wave-length 2537 Å. in the presence of 0.9 per cent formaldehyde in a phosphate buffer (pH 6.7, 0.02 M disodium hydrogen phosphate + 0.02 M potassium dihydrogen phosphate + 0.06 M sodium chloride). In these experiments the incubation times with formaldehyde were exactly the same for each sample of the different points in curve B (Fig. 1). In a second set of experiments, T1 was incubated at room temperature with 0.9 per cent formaldehyde in a phosphate buffer for the same time as the samples of the first experiments. Formaldehyde was then removed by a hundred-fold dilution in buffer, and the phages were afterwards irradiated (Fig. 1, curve A). These experiments were performed to show that formaldehyde given before irradiation does not alter the ultra-violet sensitivity of the surviving T1. The difference between curve A and curve B shows the increased inactivation-rate of irradiated T1 by formaldehyde. The number of amino-groups accessible for formaldehyde increases with greater doses of ultra-violet light, which indicates that hydrogen bonds are broken by the irradiation and that not each break leads to an inactivation of the phage.

The second aim was to determine whether the increased sensitivity to formaldehyde after ultra-violet irradiation is reversible, that is, whether the broken hydrogen bonds in the deoxyribonucleic acid rejoin. In these experiments, the phages were incubated for a given time with formaldehyde, at different times after ultra-violet irradiation. The curves drawn in Fig. 2 indicate that even after 24-hr.

Fig. 2. Inactivation-rate of T1 by formaldehyde at several times after irradiation with ultra-violet light. Abscissa, time of incubation with formaldehyde; ordinate, relative number of surviving T1. Curve parameters, doses of ultra-violet light on T1

Fig. 3. Survival of ϕ X 174 and T1 after irradiation in buffer and in a 0.3 per cent formaldehyde solution in buffer. Abscissa, time of irradiation; ordinate, relative number of surviving phages

storage in a phosphate buffer at 5° C. the increased formaldehyde-inactivation-rate of ultra-violet irradiated phages is still observed. (An increase of the reactivity of formaldehyde by the applied ultra-violet irradiation can be excluded.)

If the presumption should be correct that the rise in formaldehyde reaction-rate after ultra-violet irradiation is caused by a break of hydrogen bonds in the double-stranded deoxyribonucleic acid of T1, there should be no increase in the single-stranded deoxyribonucleic acid of ϕ X 174. Therefore, T1 and ϕ X 174 were irradiated in a buffer and, for comparison, in a 0.3 per cent formaldehyde solution. Fig. 3 shows an unchanged sensitivity in ϕ X 174 but a significant increase in T1. This gives the additional result that there also is no increased inactivation from the formaldehyde reaction with the phage protein after ultra-violet irradiation, at least in ϕ X 174.

As has been shown in Fig. 2, the hydrogen bonds broken by ultra-violet irradiation do not rejoin during a storage time of 24 hr. As it is improbable that a break of a single hydrogen bond alters the steric configuration of the deoxyribonucleic acid at this spot in such a way that the increased distance between the amino-group of one base and the ketone group of the complementary one does not allow a restitution of the hydrogen bond, a chemical change in the bases will be the cause. A possible mechanism might be the transition from the ketone- to a stable enole-configuration in the thymine, cytosine or guanine, since the enole-configuration prevents a rejoining of hydrogen bonds between the bases.

I wish to thank Miss U. Leukert for careful technical assistance.

BACTERIOLOGY

'Oxidosomes' in Bacterial Anatomy

WHEN bacterial cells are disrupted by any of the methods now in use, a considerable amount of ultra-microscopic particles is released from them, and these can be isolated by ultracentrifugation, usually for 1-2 hr. at 100,000*g*. This fraction is quite heterogeneous. The function and localization in the cell of its different components are not yet clearly known. This is probably the reason why the nomenclature of these particles is still in a rather confused state. According to different authors they have been called 'mitochondria', 'microsomes', 'particles', 'small particles', 'particulate fraction', 'ETP', etc.

It seems to me that up to now two different groups of particles have been adequately characterized: the 'ribosomes' and fragments of the cytoplasmic membrane with high enzymatic activity which I propose calling 'oxidosomes'. It is hoped that a sharp delineation of both concepts will promote the eventual discovery of other types of particulate sub-units of the bacterial cell.

Ribosomes¹ or ribonucleoprotein particles contain 40 or more per cent ribonucleic acid, and they appear to have little enzymic activity, except perhaps in protein synthesis. Their size ranges from 20 to 100 *S*. They are probably free-floating in the cytoplasm of the bacterial cell²⁻⁵ and possibly identical to the granules seen with the electron microscope in ultra-thin sections⁶. A single cell of *Escherichia coli* is supposed to contain about 10⁵ ribosomes.

The second group of particles, which has been studied to some extent, represents the small fragments from the solid cell envelope (probably the cytoplasmic membrane), and arises artificially during the disruption of the cells. They are enzymatically very active and contain, for example, many dehydrogenases and often the complete electron transport system (flavins, cytochromes, cytochrome oxidase) to oxygen. The latter particles are still designated by a variety of vague and often incorrect names, as mentioned above, and deserve an appropriate nomenclature. Since the main enzymatic function of the cytoplasmic membrane appears to consist in the oxidation of a large variety of substrates, I propose the name 'oxidosomes' for the particles derived from it. This name has been coined in analogy with other sub-cellular units, such as microsomes, lysosomes⁷, sarcosomes, episomes⁸, protosomes⁹, chromosomes, ultramicrosomes, centrosomes and kinetosomes.

These oxidosomes have been studied in several bacteria. Mitchell and Moyle¹⁰⁻¹² showed that the cytochrome- and dehydrogenase-bearing oxidosomes from *Staphylococcus aureus* are derived from the protoplast membrane. The 'hulls' of *Azotobacter vinelandii* are fragmented into oxidosomes, containing cytochromes, hydrogenase and the oxidases for reduced triphosphopyridine nucleotide, reduced diphosphopyridine nucleotide, succinate and malate^{3,4}. The particulate L-mandelic acid dehydrogenase of *Pseudomonas fluorescens*¹³ is linked to oxidosomes, since Nakada and Nozu¹⁴ recovered this enzyme in the 'ghost' fraction. The oxidosomes of *Acetobacter* have recently been studied extensively in this laboratory¹⁵⁻¹⁹. It was shown that 'protoplast' membranes contained the same enzymes as the particulate fraction¹⁵ and that intermittent ultrasonic disruption fragmented the 'hull' of intact cells into the oxidosomes¹⁶. The latter contain the cytochrome system,

several peroxidases¹⁷, catalase¹⁷, pyruvate decarboxylase, the oxidases for D- and L-lactate, acetaldehyde, ethanol and several other alcohols¹⁸, glucose, gluconate, 2-ketogluconate, galactose, xylose, glycerol, several polyalcohols, reduced diphosphopyridine nucleotide, malate and succinate.

Except for the fact that oxidosomes can be isolated by ultracentrifugation at 100,000*g* for 1-2 hr. and look like small roughly spherical granules of a few hundred Å. in diameter¹⁷ under the electron microscope, little is known of their physical properties. In view of their origin and formation, it seems possible that it is a group of particles with dimensions ranging from a few hundred Å. to the visible fragments of the 'protoplast' ghost.

Ultra-microscopic particles, containing cytochromes and other enzymes, have been isolated from several bacteria (for a review, see Alexander²⁰). However, for most of them, their localization in the bacterial cell has not yet been established, and this problem needs re-investigation in view of the properties and the origin of the oxidosomes. It can be postulated, though, that most of them will be oxidosomes. It would furthermore not be surprising that it is a general rule that most, if not all, of the aerobic bacteria would contain nearly all their cytochromes and cytochrome-linked oxidase systems on the cytoplasmic membrane.

Work along this line with the strictly aerobic chemi-autotrophic micro-organisms is in progress in our laboratory.

Interconnexion between the Protective Antigen and the Histamine-sensitizing Factor of *Bordetella pertussis*

THE interconnexion between the protective antigen and the histamine-sensitizing factor of *B. pertussis* forms the subject of earlier reports¹⁻¹¹. Results agree in that the two factors, if not identical, are in any event closely related as regards both their site in the

bacterial cell¹¹ and their activity. We have studied the behaviour of the protective antigen and the histamine-sensitizing factor under conditions which may impair *pertussis* vaccines in the course of preparation. We produced 3-day-old cultures of each of six *B. pertussis* strains of phase I on solid semi-synthetic medium. After centrifuging them, the sediment was resuspended in buffered saline so as to obtain suspensions containing 500×10^6 cells/ml. The suspensions were divided in two parts: the first was treated with 0.3 per cent formalin and kept at 37°C. for 24 hr., the second with merthiolate (1:5,000) and heated to 56°C. for 30 min. Both kinds of suspensions were then stored at +4°C. We prepared, moreover, suspensions from a mixture which contained all the six strains in equal proportions. These too were divided into formalin and merthiolate fractions (7 formalin, 7 merthiolate; 8 formalin, 8 merthiolate). Seven and 8 merthiolate seemed to be especially satisfactory in respect of protective potency and histamine-sensitizing activity: we prepared two precipitated vaccines from each of them. One contained 7 mgm./ml. of preformed aluminium phosphate gel (Holt¹²); a solution of trisodium phosphate was first added to the suspension in the case of the other vaccine and followed immediately by the admixture of a solution of aluminium chloride producing aluminium phosphate gel *in statu nascendi*. This vaccine contained likewise 7 mgm. of aluminium phosphate/ml. The addition of trisodium phosphate was observed to have raised the pH value of the mixture to 14. We determined the mouse-protection value of the suspensions and precipitated vaccines according to the prescriptions of the National Institutes of Health, Bethesda¹³, and their histamine-sensitizing activity by the method of Preston¹⁴. It is evident from Table 1 that suspensions treated with merthiolate were significantly superior to those treated with formalin as regards both mouse-protective potency and histamine-sensitizing activity. The respective values of the two factors thus ran along parallel courses, and this close correlation was

independent of whether old or fresh vaccines were employed. As regards precipitated vaccines, it is shown by our results that, however short their duration, strong alkalinity considerably impairs mouse-protective potency and histamine-sensitizing activity, while they are not affected by the preformed gel of Holt. Repeated tests confirmed these results in every respect.

It was shown in earlier experiments^{1,3} that *B. pertussis* of phase IV displays no histamine-sensitizing activity, and it is known to have no protective potency. We examined some factors which our experiments had shown to influence the protective antigen and histamine-sensitizing factor of *B. pertussis* in a similar manner. Similarity in their sensitivity to heat and in their response to different chemical agents and to variations in the phase of the bacterium has convinced us that the two factors, if not identical, are closely related and of a similar chemical structure; it is possible that they form a common antigen-complex. Since the mouse-protective potency and the histamine-sensitizing factor are affected in exactly the same manner by practically all factors which influence the efficacy of *pertussis* vaccines, it seems that—with the application of an adequate (perhaps lyophilized) standard vaccine—determination of the histamine-sensitizing factor might enable us to ascertain the real value of *pertussis* vaccines.

BIOLOGY

Embryonic Mortality induced Experimentally in the Rabbit

SYSTEMIC treatment of the pregnant doe with suitable preparations, for example stilboestrol, results in the destruction of the entire litter¹. However, a surgical approach is required in order to destroy selected embryos. Huggett and Pritchard² induced prenatal mortality in rats by crushing the fetuses with toothed forceps through the intact uterine wall at laparotomy. Later, Frazer³ employed this technique to produce a standard number of implantations by destroying any in excess of the desired number. In rabbits, Brambell *et al.*¹ also used a surgical technique to kill embryos on the 16th or 19-20th days of pregnancy; in some animals attempts were made to kill the entire complement of embryos while in others only some of the embryos were treated. The technique

consisted of perforating the uterine swellings through the antimesometrial wall of the uterus and stabbing at the embryos with a fine suture needle. Rather surprisingly several of the embryos survived this treatment. During experiments on rabbits¹ concerning the distribution of embryonic death after implantation, it became necessary to ascertain the effect of the stage of pregnancy when death occurred on the resorption of dead embryos and their placenta in litters that survived to term. Accordingly, a technique was developed whereby embryos could be killed selectively between the 7th and 17th days of pregnancy. It is the purpose of this communication to describe the application of this technique, which proved to be highly successful.

In 14 does laparotomy was performed under 'Nembutal' and ether anaesthesia, and the uterine horns were exposed. Then an incision about 4 mm. long was made through the antimesometrial wall of the selected uterine swellings, and the underlying membrane was also incised so that fluid would escape from the conceptus. In some cases very gentle digital pressure was applied to assist the escape of fluid, care being taken to avoid exteriorizing the embryo. In each animal, alternate uterine swellings were treated, but any sites that were considered to be undergoing resorption were not included. Altogether, 71 sites were treated in this manner either on the 7, 8, 10, 12, 15 or 17th day of pregnancy. Autopsy was performed on the 28th day of pregnancy, when the uterine contents were examined and weighed. Apart from one doe which was treated on the 15th day of pregnancy but aborted 7 days later, the remaining 13 does maintained the pregnancy. None of the sites which had been treated surgically contained a live foetus at autopsy and with one exception death of the embryos appeared to have occurred shortly after the operation. When the operation was performed on or before day 15, the 62 treated sites were all represented by atrophic placenta at autopsy. However, of the 9 sites treated at 17 days, only 2 were represented by atrophic placenta, whereas the other 7 contained dead fetuses. Six of these fetuses were quite small and necrotic (crown rump length approximately 15 mm.) but the remaining one, which weighed 24 gm., probably survived the operation for at least 8 days. The weights of placenta corresponding with treated sites are given in Table 1. Control placenta associated with live fetuses weighed 5-8 gm. on the 28th day of pregnancy.

It is thus apparent that the removal of fluid from the conceptus between days 7 and 17 prevents embryonic development in the rabbit. It would appear that during this period of pregnancy, when there is normally a peak of mortality², the embryo is more sensitive to environmental disturbances than

at slightly later stages when it may continue to grow even after such severe operational procedures as decapitation³. No exact information is available on the interval elapsing between treatment and death of the embryo, but in one doe examined 2 days after the operation, which was performed on the 12th day of pregnancy, the treated embryos were no longer visible. This suggests that death and resorption take place very rapidly. However, judging from the amounts of placental tissues still present at the end of pregnancy it seems that the placenta may survive for some time after the embryo dies.

I wish to thank Dr. T. Mann for reading and discussing the manuscript.

Photographic Studies of Fish Populations

FOLLOWING the work of Veevers at Plymouth, we have been using cameras for some years for studies of sea-bed and mid-water life. These electronic flash cameras are suspended from a stationary or drifting research vessel, and operated either from the ship or by triggering at a set distance from the bottom. Our frogmen have also made studies of fishing gear and fish behaviour, though their work is limited to water of less than 10 fathoms depth and to conditions of full daylight.

We wished to extend our observations of fishing gear to deep water and to night, as well as daylight, conditions. We also felt it would be useful to take repeated photographs on one spot to study changing conditions.

We have therefore developed a simple self-contained camera and flash unit, using dry batteries and operated by a clockwork timer, which can take about 200 exposures at pre-set intervals—actually 1-min. and 3-min. intervals have been used up to the present.

This camera has been used in two ways:

(a) Attached near the headline of a trawl, so as to photograph the groundrope, or the zone immediately in front of it. The first sets of results, in depths up to 65 fathoms, confirm our frogmen's observations that fish in this region are normally swimming away from the groundrope and are therefore aware of the fishing gear. These observations will be continued to determine more exactly the influence of depth and light.

(b) Placed on a heavy tripod and left on the sea-bed for subsequent recovery by means of a buoy rope. When used in this way there is less chance of fish being disturbed from their normal behaviour than when the camera is swinging below a ship. A first set of experiments was made using this technique in March on Ballantrae Bank, in the Firth of Clyde. This showed that most of the fish then present near the bottom were herring, that their numbers and shoaling pattern on that occasion did not vary with the time of day

Table 1. EFFECT OF EMBRYONIC DEATH, INDUCED SURGICALLY BETWEEN SEVENTH AND SEVENTEENTH DAY AFTER MATING, ON THE WEIGHTS OF PLACENTA RECOVERED ON THE TWENTY-EIGHTH DAY OF PREGNANCY. (MEANS $\pm$ S.E.; RANGES IN PARENTHESES)

Influence of the Organic Matrix on Crystal Type in Molluscs

THE calcium carbonate of mollusc shells occurs as calcite in some species, as aragonite in others, and certain species deposit calcite in one portion of the shell and aragonite in another portion. Various explanations have been suggested for the formation of aragonite, which is significantly less stable. Participation of the enzyme carbonic anhydrase and the influence of the protein matrix on which the crystals are deposited have both been suggested¹. We have investigated the capacity of pieces of decalcified matrix to induce aragonite formation when inserted into a mollusc which normally forms only calcite, and also under *in vitro* conditions in which calcium carbonate is normally precipitated as calcite.

Protein matrix was prepared from shells of the fresh-water clam *Elliptio complanatus*, from the marine fan shell *Atrina rigida*, and from the nacreous layer of the Japanese pearl oyster *Pinctada martensii* by decalcifying with 1 per cent sodium ethylenediamine tetraacetate at pH 5.0. In each case the shell from which the matrix was taken was aragonite. Microscopic examination of each piece of matrix showed that all crystalline material had been removed. To make certain that submicroscopic crystals did not remain, some pieces of matrix were treated further with 0.01 N hydrochloric acid. For *in vivo* studies a single piece of decalcified matrix was wrapped around a fragment of glass cover-slip and inserted between the mantle and shell of the oyster *Crassostrea virginica*, which deposits a calcite shell. The temperature of the water was 19–25° C. The inserted pieces of matrix were removed after various intervals, usually 24 hr., washed thoroughly in deionized water, and the crystals identified under the polarizing microscope. *In vitro* calcification of matrix was carried out at 25 ± 2° C. in 100 ml. of a calcium bicarbonate solution prepared from reagent grade calcium carbonate in deionized water². Pieces of decalcified matrix were placed in this solution for 25–44 hr., during which time the pH rose from 6.4 to 8.3.

Both *in vivo* and *in vitro*, aragonite crystals formed on protein matrix from aragonite shells (Table 1). Calcite crystals were also deposited on the matrix in both cases. The forms of calcite and aragonite crystals were distinct, the former being rhombic or rosette-shaped, and the latter irregular, spherulitic or hexagonal elongate. Aragonite was never found on substrates other than aragonite matrix. Tested substrates and conditions included: (1) glass cover-slip fragments inserted in *Crassostrea* (25 cases); (2) 'Formvar' plastic inserted in *Crassostrea* (4 cases); (3) decalcified calcite matrix from prismatic layer of *Pinctada* inserted in *Crassostrea* (3 cases); and (4) decalcified calcite matrix from prismatic layer of *Pinctada* tested

Table 1

Test system	Source of protein matrix	Total No. of matrix pieces analysed	No. of matrix pieces with aragonite crystals
<i>In vivo</i>	<i>Pinctada martensii</i>	4	2

	Total	25	6 or 7

* The crystals were clustered and could not be analysed. Their form was irregular and different from calcite crystals.

† Final pH 8.3.

‡ Final pH 7.3.

in vitro (10 cases). Calcite crystals only were deposited in each of these instances.

Even though freshly secreted matrix might normally induce aragonite formation in aragonite-forming molluscs, aragonite induction might well have been prevented in the present experiments by at least three conditions: (1) alteration of the original state of the aragonite matrix; (2) conversion of small aragonite crystals to calcite after deposition; (3) presence of freshly secreted matrix by the calcite-forming host mollusc. The finding of aragonite in approximately one-quarter of the cases (Table 1) is accordingly of a higher frequency than might have been anticipated.

The results point to the protein matrix as a factor determining the crystal type in molluscs. At present we have no information on molecular spacing of protein matrix of calcite and aragonite shells which might permit profitable speculation as to possible mechanisms.

This work was aided by a grant from the Office of Naval Research, United States Navy.

The Skipper (*Scomberesox saurus*) in the Southern North Sea and the Thames Estuary

THE skipper or saury pike is a pelagic fish of the open Atlantic and Mediterranean, ranging from Tristan da Cunha¹ northwards to the Gulf of Maine and the Bay of Fundy² in the western Atlantic, and to Christiana Fjord and Gjesvaer, near the North Cape, in the European Atlantic³. On the southern and south-western British coast it is of frequent, if not annual, occurrence, and catches of up to 100,000 have been reported at Mevagissey, Cornwall⁴. Farther north it has often been recorded from the Hebrides, the western Scottish coast and the Shetland and Orkney Islands⁵, but the number of records decreases noticeably on the eastern coast of Scotland. Rae (personal communication) has found a specimen off Buchan Ness, Aberdeenshire (November 21, 1957); one in the Moray Firth (December 18, 1958); a shoal at Saltburn, Cromarty Firth (December 21, 1958); one at May Island, Firth of Forth (December 1, 1958); and one from a cod stomach 12' N. St. Abbs, Berwick (February 18, 1959).

Farther south in the North Sea, records are still fewer. It has been noted from Scarborough⁴ prior to 1884, and again in 1932⁵, off Norfolk (October 1843)⁴, and at Yarmouth⁷, although it is probably more common than these few records suggest. In 1958 more than fifty were washed up at Southwold, Suffolk, and not less than twenty near Lowestoft (January 4-6, 1958); one at Corton (January 1); and one at Lowestoft (January 14) (R. W. Blacker, personal communication). In the Thames estuary, the skipper seems to have been recorded only once before, when one was found on the shore of West Mersea, Essex (December 20, 1907), as reported by Murie⁸. Writing of the occurrence of this fish on the Belgian coast, Poll⁹ regarded it as rare, and in fact cited only two records, of a number on the coast in December 1854, and of one at Ostend in 1933. Kristensen¹⁰ has, however, recorded more than a hundred in December 1955, stranded between Egmond and Texel (Holland), and three in January 1956 stranded at Den Helder, Egmond and Zandvoort. He also gives details of ten other records from the Dutch coast during the years 1909-52.

Records from various sources during the winter of 1959-60 indicate that the skipper entered the southern North Sea in larger numbers than previous records would suggest is usual. The following records have been made available to us by R. W. Blacker; two of a large number seen were caught (November 26) near Boston in the mouth of the River Witham; one alive at Corton (December 11); one alive on Lowestoft beach (December 28); two dead at Corton (December 29); a heavy stranding at Hemsby (December 31); one alive at Corton (January 1, 1960); two at Lowestoft, one at Gorleston (January 2); seventeen records between Walberswick and Yarmouth, mostly live strandings (January 2 to 12). Also during this period one of us (M. N. M.) obtained single live specimens from the River Crouch, Essex, on December 4 and 8, and a third one was found dead in the river on December 31. We have been informed by W. H. Harvey, fishery officer for the Kent and Essex Sea Fisheries Committee, that a number of skippers were caught in December by Southend and Leigh-on-Sea fishermen, while catching sprats near the East Cant Buoy, River Thames.

It seems likely from the records given here, and from those published by other authors, that in the late summer and early autumn there is often an invasion of the North Sea by shoals of *Scomberesox* through its northern entrance. Some, at least, of these fish turn southwards and may be caught later off the east coasts of Scotland and England. Others, reported in the Kattegat and the Oresund¹¹, probably represent a contingent entering the Baltic. Apparently only exceptionally do they move southwards as far as the Thames estuary. It is interesting that most of the skippers reported here were stranded, or were swimming in shallow water in the winter months of November, December and January, which seems to us to suggest that the winter cooling of the North Sea is associated with these strandings. A similar explanation has been advanced by Kristensen, who also considers that violent disturbance of the sea by storms may have some effect. In addition, he pointed out that exposure to low temperatures can result in disorientation in fish accustomed to warmer water.

We thank B. B. Rae, R. W. Blacker, W. H. Harvey and H. E. Jenner (through R. W. Blacker)

for their co-operation in reporting catches of *Scomberesox*.

Influence of Light Intensity on the Redox Potential in Leaves in cases of Iron-induced Chlorosis

AN investigation of the variation of the oxidation-reduction potential in cases of iron deficiency or calcareous chlorosis has been made in an attempt to find a relation between the redox general condition, the formation of the chlorophyll complex and its stability.

The phenomenon of iron-induced deficiency and its consequence, the low chlorophyll content, is thought to be the result of two effects¹: (1) the low content of soluble iron; (2) the influence of light. The correction of the deficiency, that is, increasing the amount of chlorophyll present, can be obtained by injecting iron or by lowering light intensity¹. After correcting the deficiency by one of the two processes, the green area of the leaf shows a redox potential higher than the normal characteristic of chlorotic material. However, the oxidation-reduction stage reached after the first process is permanent while that achieved by lowering light intensity is only temporary, since the potential returns again to that of the chlorotic conditions when a return to intense sunlight is made².

The existence of a higher redox stage after correcting the deficiency suggests the problem of discerning whether the increase of potential is a consequence or rather the cause of the formation of chlorophyll. The results obtained³ have supported the second hypothesis, that is, that for raising the chlorophyll content a certain redox-level is needed below which the actual amount cannot be increased.

Study of variation in the redox potential when light intensity is changed is one of the points considered of main interest for the interpretation of iron-induced chlorosis.

The photolability of the chlorophyll complex formed with low light intensities has been ascribed³ to the high amount of chlorophyll *b* formed, that is, to the different relation between the *a* and *b* forms of chlorophyll. But if the decomposition observed when reversing the conditions of light were only due to the different composition of the chlorophyll complex, it could be expected to stop such a decomposition as soon as the corresponding value for the green material had been reached. However, my results³ do not con-

firm such assumption, since when the change from low to intense sunlight is made the decomposition continues, yet the relation between the two forms of chlorophyll shows a similar value to that of the green leaves. It means that the decomposition of the chlorophyll complex ought to be independent of the proportion of the *a* and *b* components.

Therefore it can be deduced that while the mechanism of chlorophyll formation is actually working in the chlorotic material, its protective mechanism on the contrary fails. The protection has been ascribed to reducing substances like polyphenols³ since iron deficiency is reflected in the contents¹. Now, if such interpretation were correct it is obvious that the formation of polyphenols ought to be prior to the formation of chlorophyll; but my results show that when iron is injected into the system following the diagnostic biological method⁴ the formation of polyphenols occurs subsequent to the formation of chlorophyll.

According to this, the phenomenon of iron-induced deficiency and the protective effect of iron may be explained in the following way:

The chlorophyll present in chlorotic leaves is activated under the action of light, but only a small fraction will be stabilized while the rest decomposes. The reason is that in chlorotic conditions, ferric compound (protective agent) is present in small amounts, relative to the large number of electrons to be trapped. Then the iron will be mainly present in the ferrous form, and thence the redox potential will be low. If light intensity is lowered, only a small amount of chlorophyll will be activated and the small amount of ferric compound already present may not have at its disposal a sufficient number of electrons to pass to the ferrous form. In consequence, only very little ferrous compound will be present, and the redox potential will be higher than before. It can be easily realized that this stage cannot be permanent, because when restoring the high light intensity the conditions will be as in the beginning, namely, limited amount of ferric compound and high amount of activated chlorophyll will be present again. The only way to normalize the process is, therefore, by directly increasing the amount of ferric compound, for example, by injecting iron into the system.

ENTOMOLOGY

A Fly Larva that tolerates Dehydration and Temperatures of -270° to $+102^{\circ}$ C.

THE chironomid, *Polypedium vanderplanki* Hint., breeds in small pools formed in shallow hollows on unshaded rocks in Northern Nigeria and Uganda. The hollows are often only 5-9 in. deep, and during the rainy season they may fill and dry several times. When the pools dry up the larvae also dry up and remain in this condition until it rains again, when in about 1 hr. or so they resume feeding. The degree to which the larvae dry up depends upon the relative humidity of the air. When moisture content was

plotted against relative humidity, it was found that at 0 per cent relative humidity it was less than 3 per cent, at 60 per cent relative humidity it was 8 per cent, and at higher humidities the curve rose more steeply. In saturated air the moisture content altered from 3 to 33 per cent within 6 hr. at 25° C. The figures for moisture content are based on the assumption that the larva contains no water when its weight is constant at 106° C. The capacity to tolerate repeated dehydration is clearly of selective value to this species, and in the laboratory larvae have survived as many as 10 dehydrations to a moisture content below 8 per cent. Between dehydrations they were allowed to feed in water, usually for 1-4 days.

Larvae remain viable for long periods in the dry state. Larvae kept at room temperatures and humidities for 39 months produced normal adults when allowed to grow in water¹. For most of this period their moisture content was probably about 8 per cent; but in damp weather it may have risen to as much as 20 per cent. Recent attempts to activate 130 larvae stored for 7 years and 127 larvae stored for 10 years at room humidities were not successful. However, a high percentage of larvae stored for 3 years at room humidities and then over calcium chloride for a further 7 years recovered temporarily when placed in water: hearts beat for several hours and the larvae would respond to tactile stimuli.

Fig. 1. Skeletal muscles and tracheae of the thorax of a living larva of *Polypedium vanderplanki* that had been stored dry for ten years: three years at room humidities and a further seven over calcium chloride.

It has been shown² that active larvae tolerate water temperatures up to 41° C. for continuous periods longer than any they encounter under natural conditions. They do not survive exposure to temperatures of more than 43° C. for more than about 1 hr. The temporary pools in which the larvae live have a bottom layer of mud in which the larvae tunnel. When the pools dry, the larvae remain in their tunnels and dry out with the mud. In the dry season the shade temperatures of some of the localities in which the species is found rise to a little above 40° C. The surface temperatures of fine soils may be $20-30^{\circ}$ C. above shade temperatures. During the hottest part of the day temperatures at the surface of the dry mud may therefore be as high as 70° C., or perhaps a little higher owing to radiation from the rock sides of the hollows. However, the larvae are probably rarely exposed to such temperatures because the surface of the mud is usually protected by some plant debris and most larvae are 4-8 mm. below the surface. There is a steep fall in temperature away from the surface: even assuming a surface temperature of 80° C., the temperature at 4 mm. is 70° C. and at 8 mm. it is 60° C.³. When dried larvae

were exposed to similar temperatures, it was found that 93 per cent survived exposure to 61° C. for 14 hr. and 26 per cent survived exposure to 68° C. for 11 hr.²

It has recently been found that some larvæ will grow and successfully metamorphose after exposure to 102–104° C. for 1 min. when dry. The moisture content of such larvæ was first reduced to less than 3 per cent with phosphorus pentoxide or other dehydrating agents. They were then placed in an electric oven at 53–55° C., and the temperature raised in 10 min. to 70° C. The larvæ were then dropped on to a watch-glass in another oven at 102–104° C. The temperature of the watch-glass in the second oven had reached equilibrium with the air temperature, so that no heat was lost from the larvæ by conduction. Larvæ exposed to temperatures of over 100° C. for as much as 5 min. did not live for more than 41 hr. when afterwards placed in water, but they will recover for a short time after exposure to 106° C. for 3 hr. or to 200° C. for 5 min.

Larvæ with a moisture content of about 8 per cent survive being dropped from room temperatures into liquid air (–190° C.) or liquid helium (–270° C.). Two lots of 5 larvæ each were dropped directly into liquid air and kept there for 2 and 77 hr. respectively. All the larvæ grew normally when afterwards placed in water. Larvæ were immersed in liquid helium in a glass tube inside a metal container. Five larvæ were exposed for 3 min. and six for 5 min. All eleven grew normally when placed in water. Some of the larvæ treated with liquid air and with liquid helium were kept and in due course metamorphosed.

Active larvæ die in less than 1 min. when immersed in absolute alcohol, but when their moisture content is reduced to about 3 per cent most recover. After 24 hr. in absolute ethanol, 27 of 33 larvæ recovered. Of these all but three died within 27 hr. One died after 24 days without feeding, one that was active but not feeding was fixed after 16 days, and one metamorphosed. Ten larvæ in absolute ethanol for 7 days all recovered, and the heart of one beat for more than 55 hr. Larvæ recovered for very short periods when kept in 95 per cent ethanol for 24 hr., but none recovered when the percentage of ethanol was as low as 90. Attempts to keep dry larvæ in pure glycerol were slightly more successful: three of four larvæ in glycerol for 24 hr. survived, as did two of six in glycerol for 67 hr. and one of twelve in glycerol for 7 days.

I am grateful to Mr. R. G. Bennett, Dr. T. M. Leach, and Dr. F. L. Vanderplank for supplies of larvæ.

Effect of amputating Stylets of Mature Apterous Viviparæ of *Myzus persicae*

WHILE investigating the transmission of viruses by aphids, I observed that amputating the stylets of mature apterous viviparæ of *Myzus persicae* (Sulz.) caused them to give birth to an unusually large number of larvæ for aphids that could not feed. Indeed, for about a day the aphids produced as many larvæ as if they were feeding. To appreciate the unusual-

ness of this response, it should be understood that, as a rule, keeping *M. persicae* without food almost completely inhibits the birth of larvæ. For example, when 25 mature adults were kept singly in small vials at about 20° C., the number alive after 1, 2 and 3 days was 25, 22 and 0 respectively; and during this time 14 of the aphids produced no larvæ, 9 produced one each, and 2 produced two each (13 larvæ in all). In comparison, the same number of aphids on a host plant produced more than 100 larvæ each day; and when 25 aphids were kept in vials after amputation of their stylets, each one produced from two to several larvæ (a total of 133 larvæ the first day); the bodies of these aphids became greatly distended, and all of them died on the second day, which was about a day earlier than the controls in vials died. The larvæ born in vials were nearly all alive at the end of the day when they were counted, and those transferred to host plants developed into adults within two weeks. Thus they appeared to be normal.

Afterwards it was found that certain other treatments of the mouth parts of *M. persicae* also caused mature aphids to deposit numerous larvæ when kept without food in vials. For example, cutting off about 25µ from the distal end of one of the mandibular stylets or from the interlocked maxillary stylets caused as marked a larviposition response as did removing all four stylets (Table 1). These operations also inhibited feeding, for aphids died within 2–3 days whether kept in vials or on a host plant. Those on plants sometimes made what looked like feeble attempts to probe, but they never had their stylets inserted when they were anaesthetized with the tip of the labium affixed to the plant. Thus they seemed to be unable to insert their stylets. The mandibular stylets were separated from the maxillæ by first sliding the labium towards the head to bare the stylets¹, then supporting the bared stylets on a microrod and gently pressing across them with a single hair. This operation by itself did not cause a larviposition response (Table 1); and since this method leaves the basal part of the stylets within the labial groove, the aphid can get its stylets back together simply by sliding the labium outwards as when it withdraws from feeding. But if the stylets are taken right out of the labial groove and then separated, *M. persicae* cannot get the mandibles back alongside the maxillæ and therefore cannot reinsert all the stylets into the labial groove. This operation therefore prevents further feeding, and interestingly enough it also causes the larviposition response. The same is true if the stylets are taken out of the labial groove and the labium mutilated. It is also interesting to note here that Johnson² obtained a larviposition response after decapitation of mature adults of *Aphis fabae* Scop. These various treatments that cause larviposition in the absence of feeding may not all do so in the same way, but it is noteworthy that they have at least one other thing in common in that they also permanently inhibit feeding. When an animal carrying fully developed young can no longer feed, there are obvious evolutionary advantages to a mechanism that allows the young to be born instead of perishing within the mother.

Table 1 also presents results to show that the larviposition response following amputation of the ends of the stylets was not simply a general response to wounding. Thus there was no such response after amputation of the antennæ, their tips, a tarsus, or a leg. Cutting off the antennæ so affected *M. persicae*

Table 1. NUMBERS OF LARVÆ PRODUCED BY MATURE APTEROUS VIVIPARÆ OF *M. persicae* KEPT OVERNIGHT IN GLASS VIALS AFTER AMPUTATION OF CERTAIN PARTS

Part amputated	Larvæ from ten aphids	
	Treated	Controls
All four stylets	44	0
End of one mandible (about 25 μ)	47	0*
End of maxillæ (about 25 μ)	38	0*
Both antennæ	1	0
Tips of antennæ	4	2
One tarsus	0	2
One leg	0	2

* Controls anaesthetized and mandibular stylets separated from maxillary stylets.

that those kept in vials died more than a day earlier than the controls in vials, and though the other operations did not affect the mortality of aphids kept in vials, presumably they caused as serious wounding as the removal of the ends of the stylets, which are believed to be non-living structures.

Cutting off the ends of the stylets has also caused a marked larviposition response by non-feeding aphids of all other species thus far tested. These were mature apterous viviparæ of: *Aphis fabae* Scop., *Macrosiphum granarium* (Kirby) (= *M. avenae* Fabr.), *Macrosiphum euphorbiae* (Thom.), *Myzus ascalonicus* Doncaster, and *Myzus certus* (Wlk.). This larviposition response suggests that the functions of the stylets are more complex than is generally thought, but any discussion of its significance at this time would be rather speculative. Further studies of this response are in progress and will be published elsewhere.

That cutting off the stylets of mature aphids causes them to produce young without feeding has been overlooked in earlier work. Thus Miller³ claimed that cutting off the ends of the stylets did not prevent feeding by *Macrosiphum ambrosiae* (Thom.) or *M. granarium*. Apparently he concluded that the aphids fed because they reproduced and appeared to be feeding when viewed with a lens. In tests with *M. granarium* I found that amputating the ends of the stylets of mature apteræ caused a marked larviposition response by aphids kept in vials or on host plants. It is true that those on plants appeared to be feeding, but none could be found to have its stylets inserted; and furthermore, whether on plants or in vials the aphids died within two to three days. A second case in point is the following statement by Johnson⁴, who was discussing the colonization of plants by alatae. "It is interesting to observe that insertion of the stylets into plant tissues is not essential for either host selection or reproduction, and aphids with their stylets cut off will settle down and reproduce on suitable hosts just as aphids with intact stylets." Although this statement is quite true, it seems likely that after removal of the stylets the aphids would have settled down and reproduced on unsuitable plants and even on a non-plant surface.

I am indebted to Mr. C. V. Wade for technical assistance.

CYTOLOGY

Mitosis in *Neurospora*

In the ascus of *Neurospora*, meiosis and mitosis appear to resemble those in higher plants¹⁻⁴. However, within the mycelium of *Neurospora* and of a number of other fungi, some observers report that the conventional stages of nuclear division are lacking, that the spindle is absent, and that the nuclei divide by becoming constricted and pulling in two⁵⁻⁸. We too have found that mitosis in *Neurospora* mycelium is unlike that in higher plants and animals and that there is no spindle; but we have observed also that the nuclei are filamentous (Figs. 1-4) and that they divide by splitting longitudinally.

The mycelium of three species of *Neurospora* Shear and Dodge was grown on a cover-slip, fixed,

Figs. 1-4. Nuclei in *Neurospora* mycelia. 1, 2, 4, *N. tetrasperma*; 3, *N. crassa*. 1, post-divisional nucleus with seven chromosomes; 2, above, post-divisional nuclei; below, dividing nucleus; 3, longitudinally dividing nucleus; 4, a loop and a spiral-shaped nucleus in the conidium before dividing, three V-shaped nuclei in the hypha. ($\times 1,750$)

hydrolysed, stained in Giemsa and examined with a Zeiss microscope with 'Optovar' to give an initial magnification of 2,500. By this method, the chromosomes in the mycelium of *Neurospora tetrasperma*, *N. crassa* and *N. sitophila* were revealed. As in the ascus there are seven chromosomes in each species.

The chromosome groups most suitable for counting appear at first glance to be at metaphase, but in reality there are no such stages of mitosis in these nuclei. The chromosomes are arranged in linear series upon a filament (Fig. 1). McGinnis⁹ has previously observed similar nuclei in the basidium of *Puccinia graminis*. In *Neurospora* the chromosomes are most easily counted when the filament is coiled within the nuclear membrane.

We have observed the following types of nuclei which we believe to be consecutive stages in mitosis: (1) a network within a spherical membrane; (2) an elongated network free of the membrane; (3) a narrow thread; (4) a thread longitudinally split (Fig. 3); (5) two separate daughter threads; (6) a shortened and thickened filament with distinct chromosomes; (7) a similar filament coiled within a membrane.

Masses of nuclear strands may occur in the lumen of hyphae and also passing through their transverse septa. The identity of the individual nuclei is lost in the tangle (Fig. 2). In such masses, nuclear components may become interchanged, and hyphae may become unlike genetically.

A detailed report of this work will be published elsewhere.

This work was made possible by grants from the National Research Council, Ottawa, Canada.

Amphiplasty in *Ribes*

SEVERAL authors have reported that in *Ribes nigrum* L. (black currant) and *R. grossularia* L. (gooseberry), as in all other *Ribes* species so far investigated, a pair of satellited chromosomes is constantly present¹⁻³. However, in 1957 it was noticed that only one satellite could be seen at metaphase in root tip cells of a black currant × gooseberry hybrid. Two further black currant × gooseberry hybrids have since become available for study and in both of these only one satellite is visible in root tip cells. The presence of two satellited chromosomes in two black currant and two gooseberry varieties (Baldwin and Boskoop Giant black currants, Broom Girl and Green Ocean gooseberries), parents of two of the hybrids mentioned above, has been confirmed. Evidently, in the hybrid, one of the parental satellites disappears. This phenomenon has been described in interspecific hybrids of *Crepis* by Navashin⁴, who includes this and other chromosome

changes due to hybridization under the term amphiplasty^{4,5}.

Further work in progress on amphiplasty in *Ribes* species hybrids will be reported elsewhere.

GENETICS

A Screening Technique for Photosynthetic Mutants in Unicellular Algae

IN conjunction with experiments concerned with the genetics of photosynthesis in the sexually reproducing, unicellular, green alga, *Chlamydomonas reinhardtii*¹ it became necessary to devise a technique to screen for mutants which were blocked in some phase of their photosynthesis. In the technique to be described here the inability to fix carbon dioxide in the light was taken as a requirement of a non-photosynthetic mutant.

There are forty-two mutants of *C. reinhardtii* which cannot grow in the light unless the minimal medium² is supplemented with sodium acetate, and it was considered that certain of these mutants might not be able to fix carbon dioxide in the light. Rather than measuring carbon dioxide fixation individually for each mutant by the usual method³ it was possible to assay for their ability to fix carbon dioxide while they were growing in colonies on agar medium contained in Petri dishes.

Petri dishes containing colonies of wild-type and several acetate mutants were inverted over a small watch-glass. Acetic acid (0.1 ml. of a 1 N solution) was pipetted into each watch-glass followed by the addition of 0.3 ml. of carbon-14 labelled sodium bicarbonate (2.5 µc./ml.). The operations were carried out in a hood. After the addition of the sodium bicarbonate the light from two 150-watt reflector floodlights was directed toward the Petri dishes. The light was allowed to remain on for 5 min. during which time a comparable set of colonies was exposed to carbon-14 labelled carbon dioxide in the dark as a control.

At the end of 5 min. the lights were turned off, and the colonies were replicated to filter paper. Each of the filter papers was exposed to the fumes of concentrated hydrochloric acid for 3 min. in order to drive off any unfixed carbon dioxide. Radioautographs were made of the replicated colonies using Kodak No-Screen X-ray film and were developed after exposure for one week. The ability of wild-type or a mutant to fix carbon dioxide was seen by the darkening of the emulsion of the film at a position which coincided with the position of the colony on the filter paper. The controls run in the dark gave negative radioautographs.

In this manner it was possible to screen rapidly the forty-two acetate-requiring mutants of *C. reinhardtii* for their ability to fix carbon dioxide. Fig. 1A shows the filter paper replica of colonies of wild-type and seven different acetate mutants. Fig. 1B shows the radioautograph of the colonies. It appears from

Fig. 1. Radioautographic technique used in screening for mutants which do not fix carbon dioxide. A, Filter paper replica of colonies which were exposed to $^{14}\text{CO}_2$ in the light; B, the radioautograph of the colonies. The wild type (WT) and seven acetate-requiring mutants are shown here. It is seen that ac-21 gives a negative radioautograph.

the radioautograph that ac-21 does not fix carbon dioxide. Subsequent, more direct tests have revealed that the rate of carbon dioxide fixation in this mutant is some ten-fold less than that of wild-type and that the genetic block to photosynthesis lies in the process of photosynthetic phosphorylation¹.

Additional photosynthetic mutants have been obtained in the manner described here by screening colonies which had been derived from cells irradiated with ultra-violet light. Cells of wild-type were plated (1.5×10^4 cells per plate) to minimal agar which had been supplemented with sodium acetate. The cells were then irradiated with a dose which permitted 1 per cent survival. Following irradiation, the Petri dishes were placed in the dark for 12 hr., after which the colonies were allowed to develop at 25° C. and at a light intensity of 250-foot-candles from daylight fluorescent lamps. After 72 hr. the colonies were replica-plated to minimal agar supplemented with sodium acetate and to minimal agar supplemented with sodium acetate and yeast extract. When colonies had formed on these plates (usually within 72 hr. after replication) those growing on the medium supplemented with sodium acetate alone were tested for carbon dioxide fixation according to the method described above, while those growing on the medium supplemented with both sodium acetate and yeast extract were placed in the dark to await the results of the radioautographs. Those colonies giving a negative radioautograph were picked from the doubly supplemented medium in order to establish stock cultures. These in turn were tested for their inability to grow on minimal medium and to fix carbon dioxide as determined by more usual means.

The advantage of the technique described here lies in the rapidity and economy with which it is possible to screen large numbers of colonies for their ability to fix carbon dioxide. The technique should be feasible in any alga which can be handled in a manner similar to that of *C. reinhardtii*. In addition, it should be possible to adapt the technique for most micro-organisms which can fix carbon dioxide when it is provided in the way described here.

This work was supported by grants from the National Science Foundation and the U.S. Public Health Service.

Elective Production of Thymine-less Mutants

THYMINE-LESS (*thy*⁻) mutants of micro-organisms have not been easy to obtain. They die rapidly in the absence of thymine¹ so that, when penicillin is used to concentrate them, none survives the treatment. To discover them after mutagenic treatment requires direct detection methods and this, in turn, either good fortune^{2,3} or a very high frequency of *thy*⁻ mutants among the survivors⁴. We have recently discovered a method whereby *thy*⁻ mutants of some strains of *Escherichia coli* 15 and K 12 can be produced in frequencies of the order of 50 per cent. Although no success was obtained with *Salmonella typhimurium*, the method seems to involve the general principle of differential growth-rates. With *E. coli* both the *thy*⁻ and *thy*⁺ strains are inhibited by aminopterin, but it seems that only in the *thy*⁻ can thymidine completely overcome that inhibition.

The strains used were *E. coli* 15 *h*⁻ (histidine-less), its colicine-resistant T-phage-sensitive derivative (15 *h*-CR⁵), and the wild type and various mutants of *E. coli* K 12 (a prototrophic, streptomycin sensitive derivative of HfrH, lysogenic for λ ; W 1177 and CR 34, both of which are F⁻ and require threonine, leucine and vitamin B₁ although they differ in other genetic markers). The chemically defined medium employed was a modified Gray and Tatum medium⁶; the various strains were grown in this, supplemented as needed, with: L-histidine, 25 $\mu\text{gm./ml.}$ (H⁺ medium); DL-threonine, 200 $\mu\text{gm./ml.}$ (Thr⁺); L-leucine, 20 $\mu\text{gm./ml.}$ (Leu⁺); vitamin B₁, 0.2 $\mu\text{gm./ml.}$ (B₁⁺); thymine (Nut. Biochem. Corp.) 40 $\mu\text{gm./ml.}$ (Thy⁺); thymidine (Cal. Corp. Biochem. Res.) 20 $\mu\text{gm./ml.}$ (Td⁺).

For treatment the medium was also supplemented (G8 medium) with 12 of 14 substances the syntheses of which are thought to be inhibited by aminopterin⁷ (thymidine and vitamin B₁₂ were omitted, the latter for no good reason). The complete medium (YECA) consisted of a modified Gray and Tatum medium supplemented with 0.5 per cent Difco yeast extract, 0.5 per cent NZ-case and 0.5 per cent dextrose.

The treatment can be illustrated with the example of 15 *h*-CR. A single colony of this strain was inoculated into 5 ml. of G8 medium and incubated on a rotator at 37° C. overnight, during which time growth usually ceased at a level of 10^8 cells per ml. because of the exhaustion of dextrose (0.05 per cent). The cell suspension was diluted 10^{-1} and 0.1 ml. was added to 4.5 ml. of G8 medium along with 0.5 ml. of a solution of 2 mgm. aminopterin (Cal. Corp. Biochem. Res.)/ml. The mixture was incubated on a rotator at 37° C. for 24 hr., during which time the number of viable cells decreased to 10^2 – 10^3 /ml. (c. 10^{-3} survival). Then 0.5 ml. of a solution of 2 mgm. thymidine (or thymine)/ml. was added and incubation continued, whereupon the cells began to grow. After 48–72 hr., full turbidity was achieved and the suspension was washed twice with saline, diluted and plated on YECA agar medium supplemented with 10 $\mu\text{gm.}$ thymidine/ml. (YECA-Td⁺). All *thy*⁻ mutants could not use thymine in the presence of YECA but would grow when thymidine was present. On chemically defined medium either compound supported growth equally well.

Colonies appearing on YECA-Td⁺ agar medium were replicated on to H⁺ and H⁺Td⁺ agar. Between 10 and 50 per cent were *thy*⁻ mutants, all retaining their *h*⁻ and (on the basis of limited tests) CR characteristics. When 0.5 ml. of a solution of 2 mgm.

5-bromo-deoxyuridine (Cal. Corp. Biochem. Res.)/ml. was also added to the G8 medium at the time of thymidine addition, up to 80 per cent of the population might be *thy*⁻.

Strain K 12 behaved somewhat differently from 15. Its derivatives grew more slowly in the chemically defined medium. When after some delay (1 day for HfrH and CR 34, 2 days for W 1177 and 3 days for wild type) they did reach full turbidity, a final concentration of 200 or 500 μ gm. aminopterin/ml. was employed. Afterwards when thymidine and 5-bromo-deoxyuridine were added, it took 2 days for CR 34 and 4 days for W 1177, HfrH and wild type to reach full turbidity. The percentage of *thy*⁻ mutants present varied as follows:

	CR 34	HfrH	W 1177	Wild type
200 μ gm. aminopterin/ml.	—	6.1	16	—
500 μ gm. aminopterin/ml.	78	44	—	0.2

A preliminary analysis of a number of questions has been made with the following results:

(1) The pre-treatment with aminopterin is unnecessary; (2) the appearance of *thy*⁻ mutants is not due to differential survival in aminopterin, because they appear without pre-treatment and die in the presence of aminopterin about as fast as *thy*⁺; (3) the *thy*⁻ mutants are the only ones produced by this treatment in detectable frequencies; the original markers of the treated bacteria are not observed to change in the *thy*⁻ produced—for example, *h*-CR bacteria remain *h*-CR; (4) the mutants produced are stable to an ordinary extent; recombination experiments with the K 12 strains indicate that the *thy*⁺ marker is transferred from the Hfr to the F⁻ parent, which result would seem to indicate that the genetic unit concerned is not extra-chromosomal; (5) the appearance of *thy*⁻ mutants seems not to be due to mutation induced by aminopterin but rather to the selective overgrowth after the thymidine has been added.

STATISTICS

Time-Dependent Results for a Dam with Ordered Poisson Inputs

Let the content $0 \leq Z(t) < \infty$ of a dam at time $t \geq 0$, fed by an input $0 \leq X(t) < \infty$ in time t , and subject to a steady release at constant unit rate, be defined by the equation:

$$Z(t + \delta t) = Z(t) + \delta X(t) - (1 - \eta)\delta t \quad (1)$$

where $\eta\delta t$ ($0 \leq \eta \leq 1$) is the time during t , $t + \delta t$ that the dam is empty. $X(t)$ is such that the arrival

times of inputs form a Poisson process with parameter λ , the inputs themselves being of constant sizes α_1, α_2 , and always arriving in this order ($\alpha_1, \alpha_2 > 0$).

The process $Z(t)$ is Markovian when the number of inputs up to t is known. If we define:

$$F_i(z_0, z, t) = \Pr\{Z(t) \leq z, X(t) = n(\alpha_1 + \alpha_2) + \delta_{i1}\alpha_1 | Z(0) = z_0\} \quad (2)$$

for $n = 0, 1, 2, \dots$; $i = 1, 2$; δ_{i1} being the Kronecker delta, the transition distribution function of the dam content is:

$$F(z_0, z, t) = \Pr\{Z(t) \leq z | Z(0) = z_0\} = F_1(z_0, z, t) + F_2(z_0, z, t) \quad (3)$$

It is readily shown the $F_i(z_0, z, t)$ satisfy differential-difference equations:

$$\frac{\partial F_i}{\partial t} - \frac{\partial F_i}{\partial z} = -\lambda\{F_i(z_0, z, t) - F_j(z_0, z - \alpha_i, t)\} \quad (0 \leq z < \infty) \quad (4)$$

where $i, j = 1, 2$ but $i \neq j$, and $F_i(z_0, z, t) = 0$ if $z < \max(0, z_0 - t)$; these are similar to Takács' equation for the distribution function of the process in the case $\alpha_1 = \alpha_2$.

The Laplace-Stieltjes transforms of (4) lead to integral equations for the transforms of the $F_i(z_0, z, t)$, which also involve the probabilities of emptiness $F_i(z_0, 0, t)$ ($i = 1, 2$). These do not appear to yield readily to solution. Direct probabilistic considerations will, however, lead to explicit results for the $F_i(z_0, z, t)$, and hence for the distribution function $F(z_0, z, t)$.

The probabilities of first emptiness $g_i(z_0, T_n)$ of the dam after n inputs starting with an input α_1 , where $T_n = z_0 + [\frac{1}{2}(n+1)]\alpha_1 + [\frac{1}{2}n]\alpha_2$ ($n = 0, 1, 2, \dots$), are known. In some connected work, I have⁸ obtained them recursively using a modified form of Kendall's⁹ equation:

$$g_1(z_0, T_n) = \sum_{j=0}^{\infty} \sum_{i=0}^{\infty} e^{-\lambda z_0} \frac{(\lambda z_0)^{2j+i}}{(2j+i)!} g_{1+i}(j(\alpha_1 + \alpha_2) + \delta_{i1}\alpha_1, T_n - z_0) \quad (5)$$

where $g_i(0, 0) = 1$, $g_i(w, w + r\alpha_1 + s\alpha_2)$ is obtained from the formula for $g_i(w, w + s\alpha_1 + r\alpha_2)$ by interchanging α_1 and α_2 ($s - r = 0, 1$), and $g_i(w, T) = 0$ if $T < w$ ($i = 1, 2$) for any $w > 0$, or $w = 0$ for any $T > 0$. A simpler evaluation of these by the method of truncated generating functions⁴ is also given.

It is found that:

$$g_1(z_0, T_n) = \begin{cases} e^{-\lambda z_0} & (n = 0) \\ e^{-\lambda T_n} \frac{\lambda^n}{n!} z_0 \sum_{i=0}^{n-1} c_{ni} z_0^i & (n \geq 1) \end{cases} \quad (6)$$

where the coefficients c_{ni} can be obtained for any value of $n \geq 1$. In a recent paper Gani and Pyke⁸ have also derived some simple inequalities for the $g_1(z_0, T_n)$ where $\alpha_1 > \alpha_2$.

Combinatorial arguments establish that:

$$F_i(z_0, 0, t) = \sum_{r=0}^{\infty} g_1(t - r(\alpha_1 + \alpha_2) - \delta_{i1}\alpha_1, t) \quad (7)$$

where $g_1(t - r(\alpha_1 + \alpha_2) - \delta_{i1}\alpha_1, t) = 0$ if $r(\alpha_1 + \alpha_2) > t - z_0 - \delta_{i1}\alpha_1$, and after a transformation ($u = z + t$, $t = t$), the equations (4) may be solved jointly step by step in the consecutive intervals:

$$[\frac{1}{2}(n+1)]\alpha_1 + [\frac{1}{2}n]\alpha_2 \leq z < [\frac{1}{2}(n+2)]\alpha_1 + [\frac{1}{2}(n+1)]\alpha_2 \quad (i, j = 1, 2; i \neq j)$$

It is found that, in these intervals :

$$F_i(z_0, z, t) = \sum_{r=0}^{\infty} e^{-\lambda\{[k(r+1)\alpha_i + [4r]\alpha_j - z\}} \times \\ \left(\lambda \left\{ \left[\frac{1}{2}(r+1) \right] \alpha_i + \left[\frac{1}{2}r \right] \alpha_j - z \right\} \right)^r / r! \times \\ \left\{ \frac{\delta_r}{2}, \left[\frac{r}{2} \right] F_i(z_0, 0, z + t - \left[\frac{1}{2}(r+1) \right] \alpha_i - \left[\frac{1}{2}r \right] \alpha_j) + \right. \\ \left. (1 - \frac{\delta_r}{2}, \left[\frac{r}{2} \right]) F_j(z_0, 0, z + t - \left[\frac{1}{2}(r+1) \right] \alpha_i - \left[\frac{1}{2}r \right] \alpha_j) \right\} \quad (8)$$

where $i, j = 1, 2$, but $i \neq j$. From these, the distribution function $F(z_0, z, t)$ of (3) can be obtained; in the case $\alpha_1 = \alpha_2$, this naturally reduces to the form previously given by Gani and Prabhu⁶.

The method outlined is equally applicable to the case of $p > 2$ ordered inputs $\alpha_1, \dots, \alpha_p$. There is a corresponding increase in the complexity of the equations for the associated probabilities of first emptiness starting with an input α_1 , as well as for the distribution function of the process.

Plant Population and Crop Yield

UNDER the above title, Holliday¹ has recently published an equation which describes in a number of cases the relationship between yield and density in crop plants. In its simplest form this relationship is :

$$1/w = A\rho + B \quad (1)$$

where w is the yield per plant, ρ is the number of plants per unit area and A and B are constants. This equation was used (with these symbols) by Shinozaki and Kira² in 1956. An equivalent relationship connecting the total yield per unit area, $y = \rho w$, with the spacing per plant, $s = 1/\rho$, namely :

$$y = \frac{1}{A + Bs} \quad (2)$$

was proposed independently by De Wit and Ennik in 1958³. These authors concede that the formula may not apply at high plant densities, and Holliday has directed attention to its limitations at very low plant densities, and accordingly has proposed a modification of equation (1). Appropriate modifications for both extremes are considered by Shinozaki and Kira⁴. Holliday further points out that even his modified equation cannot describe adequately total yield/plant density relationships where the form of the curve is parabolic, that is, where a certain plant population gives higher yields than either lower or higher populations. This type of curve, it is claimed, is typical of situations where yield is a function of reproductive growth, whereas curves that reach a stable maximum with increasing plant density are typical of yield of vegetative growth, and are

defined by equations similar to or derived from equation (1).

There appear to be exceptions to this generalization; thus the data of Wiggins⁵ for the yield of threshed beans from soybean are adequately described by equation (1), whereas our own observations (unpublished) show that the yields of onions and lettuce frequently are not.

The Japanese contribution to knowledge of this subject does not appear to be widely known, and we therefore feel that the references given below⁶ may be useful. Kira and his co-workers have shown how equation (1) can be derived from the logistic equation for plant growth together with certain other plausible assumptions, and have studied how the parameters in the equation change with time.

Hozumi, Kira and Shinozaki⁶ have developed the application of equation (1) to cover the effects of any growth factor in suboptimal supply using the form :

$$\frac{1}{w} = \frac{A}{f} + B$$

where f is the amount of a factor supplied. They have developed the generalization for several factors varying simultaneously, using multilinear forms in the inverses of the amounts of the factors. Thus for two factors of amounts f_1 and f_2 , they put :

$$\frac{1}{w} = \frac{A_1}{f_1} + \frac{A_2}{f_2} + \frac{A_{12}}{f_1 f_2} + B$$

and show that this model successfully describes the joint effect of light intensity and nutrient concentration on the growth of *Lemna minor*⁷, and the joint effect of light intensity and density on the growth of *Hibiscus moscheutos*⁸. Although Kira and his co-workers have apparently successfully used equation (1) and their generalization of it for a number of species, we find that the relation :

$$\frac{1}{w\theta} = A\rho^{\theta} + B \quad (3)$$

where θ is some positive quantity usually less than unity, frequently gives a strikingly better fit to data from spacing experiments. Equation (3) can be derived by analogous arguments to those of Kira *et al.*, the logistic equation being replaced by a generalization described by Richards⁹. By allowing the power of ρ in (3) to exceed that of w , a model can be obtained in which the yield per unit area shows a maximum at a certain finite density. A detailed account of this work will be published elsewhere.

FORTHCOMING EVENTS

(Meetings marked with an asterisk * are open to the public)

Monday, October 24

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 4 p.m.—Dr. J. Valance-Owen: "Insulin Activity and Antagonism in Plasma".*

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. R. A. French: "Geography and Geographers in the Soviet Union".

ROYAL INSTITUTION, LIBRARY CIRCLE (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. H. R. Bishworth: "Herbals and Herbalists, Ancient and Modern".

SOCIETY OF CHEMICAL INDUSTRY, CORROSION GROUP (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Cathodic Protection Panel Meeting (Brains Trust).

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION, at Savoy Place, London, W.C.2), at 6.30 p.m.—Mr. A. Porter: "Southern Region, Kent Coast Electrification Scheme—Power Supply Apparatus" (Chairman's Address).

Tuesday, October 25

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. A. Armitage: "Some Observatories and Observers of the Seventeenth Century".*

INSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENT AND CONTROL SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. E. H. Cooke-Yarborough and Mr. R. O. M. Barnes: "Rapid Methods for Ascertaining whether the Activity of a Weak Radioactive Sample Exceeds a Predetermined Level".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. C. H. Andrews: "The Common Cold".* (Second of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. Stuart Hampshire: "Feeling and Expression" (Inaugural Lecture).*

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. F. S. Dainton, F.R.S.: "The Relationship Between Structure and Polymerisability of Monomers".

Wednesday, October 26

PHOTOBIOLOGY GROUP (at Queen Mary College, Mile End Road, London, E.1), at 11 a.m.—Report on work in progress in the Botany Department, Queen Mary College. Afternoon Session: Reports from the International Congress of Photobiology held in Copenhagen, July 31st–August 5th, 1960.

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Dr. J. H. Wilkinson: "Biochemistry of the Thyroid".*

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 3 p.m.—Annual General Meeting. Wing-Commander R. W. Anderson, O.B.E.: "The Philosophy of Navigation Today" (Presidential Address).

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS AND COMMUNICATIONS SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. T. B. D. Terrell: "Channeling—A Sketch" (Chairman's Address).

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Prof. Owen A. Saunders: "The Scientist's Contribution to Mechanical Engineering" (Presidential Address).

SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMISTRY GROUP (at "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Discussion on "Analytical Aspects of Corrosion" opened by Mr. H. C. J. Saint.

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at Goldsmiths' College, Lewisham Way, London, S.E.14), at 7 p.m.—Mr. R. B. Collins: "Modern Colour Photographic Processes".*

Wednesday, October 26—Thursday, October 27

BRITISH INSTITUTION OF RADIO ENGINEERS (at the School of Pharmacy, Brunswick Square, London, W.C.1), at 10.45 a.m. on Wednesday and 10 a.m. on Thursday—Symposium on "New Components".

Thursday, October 27

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Dr. V. P. Whitaker: "The Subcellular Localisation of Neurohormonal Agents".*

UNIVERSITY OF LONDON INSTITUTE OF EDUCATION (in the Great Hall, Goldsmiths' College, New Cross, London, S.E.14), at 5 p.m.—Mr. W. G. Stone: "Some Possible Developments in the Youth Service".* (Final lecture in a series on "The Future of Education".)

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. A. Hewish: "The Principles and Operation of Large Radio Telescopes".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. Wilson Smith: "Virus Flocculation Reactions".* (Third of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

CEMENT AND CONCRETE ASSOCIATION (at the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Mr. E. V. Finn and Mr. K. F. Shadbolt: "Structural Consideration of a New Animal Feed Mill in Belfast, Northern Ireland".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the BOROUGH POLYTECHNIC CHEMICAL SOCIETY, at the Borough Polytechnic, Borough Road, London, S.E.1), at 7 p.m.—Prof. O. W. Davies: "Some Aspects of Ion Exchange".

Friday, October 28

INSTITUTE OF BIOLOGY, PARASITOLOGY GROUP (in the Zoology Department, Birkbeck College, Malet Street, London, W.C.1), at 10.30 a.m.—Meeting on "Recent Advances in Fields of Parasitological Research".

LINNEAN SOCIETY and the BRITISH MYCOLOGICAL SOCIETY (in the Lecture Theatre of the British Museum (Natural History), Cromwell Road, London, S.W.7), at 8 p.m.—Miss Guilelma Lister Centenary Meeting.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. Maurice Neville Hill: "Exploring the Ocean Floor".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (preferably with teaching and/or industrial experience) IN PHYSICS at the City College of Technology, Byrom Street, Liverpool 3, to teach to graduate level—The Director of Education, City of Liverpool Education Committee, 14 Sir Thomas Street, Liverpool 1 (October 28).

ASSISTANT IN ZOOLOGY—Secretary to the University Court, The University, Glasgow (October 31).

ASSISTANT LECTURER IN ZOOLOGY—The Registrar, The University, Leicester (November 1).

ASSISTANT LECTURER IN PHYSICS—The Registrar, The University, Sheffield (November 5).

LECTURER IN PHARMACOLOGY—Joint Clerk to the University Court, Queen's College (University of St. Andrews), Dundee (November 5).

LECTURER IN PSYCHIATRY—The Registrar, The University, Sheffield (November 5).

LECTURER (with research experience in physical oceanography or in an appropriate branch of physics or mathematics) IN PHYSICAL OCEANOGRAPHY at the Marine Biology Station—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (November 7).

RESEARCH ASSISTANT (with Ph.D. or equivalent research experience) FOR WORK ON THE ORGANIC CHEMISTRY OF FREE RADICALS—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (November 7).

LECTURER (with a university degree in forestry and practical experience of forestry in Great Britain) IN THE DEPARTMENT OF FORESTRY—The Secretary, The University, Edinburgh (November 8).

ASSISTANT LECTURER (with medical qualifications registrable in this country) IN ANATOMY—The Registrar, The University, Manchester 13 (November 12).

DIRECTOR for an important RESEARCH STATION with a staff of over 30 engaged on ECOLOGICAL STUDIES—The Nature Conservancy (B), 19 Belgrave Square, London, S.W.1 (November 12).

VETERINARY PARASITOLOGIST (graduate in science or agricultural science or science with zoology as a major subject, or equivalent qualifications) at THE MCMASTER LABORATORY, Division of Animal Health, C.S.I.R.O., Sydney, Australia, to undertake general duties in parasitology, including studies of the ecology of nematode larvae recovered from pastures and ruminal contents of sheep and the testing of new anthelmintics against nematode infection of sheep—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 202/179 (November 12).

BOTANIST (Plant Physiologist), Division A (with a good honours degree in botany or equivalent qualification, and at least two years research experience in the field of plant physiology) in the Botanical Division, Rubber Research Institute of Malaya, Kuala Lumpur, to investigate the occurrence and function of natural auxins and other growth factors in the rubber tree, *Hevea brasiliensis*—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Commonwealth Institute, Imperial Institute Road, London, S.W.7 (November 15).

CHAIR OF PHYSIOLOGY IN THE FACULTY OF MEDICINE, University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 15).

SENIOR LECTURER or LECTURER IN VETERINARY PHYSIOLOGY AND BIOCHEMISTRY at the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 15).

LECTURER IN APPLIED MECHANICS; a LECTURER IN THERMODYNAMICS; and a LECTURER IN STRUCTURES—The Registrar, The University, Leicester (November 18).

LECTURER or ASSISTANT LECTURER (preferably with research interest in marine biology or comparative physiology) IN ZOOLOGY at

the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 19).

OFFICIAL FELLOW IN MATHEMATICS—The Principal, Hertford College, Oxford (November 26).

RESEARCH FELLOW (Pharmacologist, Biochemist or Organic Chemist with biological experience, and of Ph.D. standard) FOR WORK IN THE FIELD OF CHEMOTHERAPY—The Secretary, Medical Research Council of Ireland, 50 Merrion Square, Dublin (November 26).

ASSISTANT LECTURER IN PHYSICAL CHEMISTRY—The Registrar, Massey Agricultural College (University of New Zealand), Palmerston North, New Zealand (November 30).

CHAIR OF PURE MATHEMATICS—The Registrar, University College, Singleton Park, Swansea (November 30).

LECTURER or ASSISTANT LECTURER IN GEOGRAPHY at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 30).

PROFESSOR OF AGRICULTURE AND DIRECTOR OF THE COLLEGE FARM—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (December 1).

ASSOCIATE PROFESSOR OF MEDICINE at the University of New South Wales, Australia—The Agent-General for New South Wales, 58-57 Strand, London, W.C.2 (Australia and London, December 12).

CHAIR OF PHILOSOPHY at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, December 31).

ASSISTANT EXPERIMENTAL OFFICER (familiar with elementary chemical techniques and possessing H.N.C. or equivalent, or, if under 22, qualifications leading to the above) in the CHEMICAL MICROBIOLOGY DEPARTMENT for work on cheese flavour—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref. 60/15.

ASSISTANT LECTURER (graduate in chemistry, and preferably with experience in the food industry) for duties which will include the TEACHING OF CHEMISTRY AND FOOD QUALITY CONTROL—The Principal, National College of Food Technology, St. George's Avenue, Weybridge, Surrey.

BIOCHEMICAL TECHNICIAN (preferably with experience of microbiological techniques)—Head of the Department of Physiology and Pharmacology, Chelsea College of Science and Technology, Manresa Road, London, S.W.3.

BIOCHEMIST (whole-time, non-resident) for hospital biochemical work in the Mansfield Area Pathology Service—The Hospital Secretary, King's Mill Hospital, Sutton-in-Ashfield, Notts.

BROADCASTING AND FILM LIAISON OFFICER (with a good general scientific background, familiarity with 16 mm. film production methods and equipment, and some knowledge of broadcasting techniques) at the Headquarters of the Department of Scientific and Industrial Research, London, S.W.1, for duties which will be concerned mainly with liaison between research organisations and film companies. The work also includes projection and care of equipment, selection and editing of film for T.V. use and promotion of films—Manager (P.B. 3158), Ministry of Labour, Professional and Executive Register, Atlantic House, Farringdon Street, London, E.C.4.

CHEMIST or BIOCHEMIST (with a good honours degree in science or equivalent qualification) to undertake research on the quality of protein in animal feeding stuffs—The Secretary, Rowett Research Institute, Bucksburn, Aberdeen.

GENETICIST, Principal Scientific Officer or Senior Scientific Officer grade (with Ph.D. or a good honours degree with at least two years postgraduate research experience in microbiology) to TAKE OVER THE GENETICS SECTION—The Secretary, Research Institute (Animal Virus Diseases), Pirbright, Surrey.

LABORATORY TECHNICIANS AND INSTRUMENT MAKERS for established posts in RESEARCH and TEACHING LABORATORIES concerned with electronics, vacuum physics, ultrasonics, X-rays, solid state physics, etc.—Head of the Physics Department, Northampton College of Advanced Technology, St. John Street, London, E.C.1.

MICROBIOLOGIST (with research experience) FOR WORK ON RADIATION-INDUCED MUTATIONS IN MICROBIAL POPULATIONS—The Administrator, Radiobiological Research Unit, Medical Research Council, Harwell.

ORGANIC CHEMIST (with an honours degree in chemistry or biochemistry) to assist with research into the chemistry of micro-organisms—Prof. J. H. Birkinshaw, Department of Biochemistry, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1.

PHYSICAL METALLURGIST or PHYSICIST (graduate, with research experience) in the Physical Metallurgy Division, Department of Mines and Technical Surveys, Canada, to work with a group carrying out fundamental investigations in metal physics—Dept. D.M.T.S., National Employment Service of Canada, 61 Green Street, London, W.1.

READER IN ANALYTICAL CHEMISTRY—The Academic Registrar, Loughborough College of Technology, Loughborough, quoting 14/2/A.F.

RESEARCH FELLOW (with a higher degree or research experience), or an **ASSISTANT** (with a degree in chemistry or physics) in POLYMER CHEMISTRY for work of a physicochemical nature—The Registrar, Bradford Institute of Technology, Bradford, 7.

RESEARCH FELLOWS and RESEARCH ASSISTANTS (with a good honours degree in pharmacy or other allied subjects) in the DEPARTMENT OF PHARMACY—The Registrar, Bradford Institute of Technology, Bradford 7.

RESEARCH FELLOWS (with a first- or second-class honours degree, evidence of high standard of ability in research, and at least two years postgraduate research experience, three years for senior fellows) at GOVERNMENT SCIENTIFIC ESTABLISHMENTS, in a very wide range of topics, especially in the physical sciences and in various branches of biology—The Civil Service Commission, 17 North Audley Street, London, W.1, quoting 8/5060/60.

TECHNICIAN (preferably with experience in microbiology) in the SCIENCE DEPARTMENT, to be responsible for the preparation of glass materials and maintenance of stock cultures, and general duties—The Principal, Ewell County Technical College, Reigate Road, Ewell, Bpsom, Surrey.

THE LEARNED SOCIETY, THE ARTS AND THE SCIENCES

"It is the duty of the Royal Society", said Sir Cyril Hinshelwood, in concluding his tercentenary address, "to maintain within the larger community the smaller one in which creative activity can flourish. Its members owe a multiplicity of loyalties, none of which can be fulfilled without the others: to mankind in general, to their native land, and to the Royal Society itself". "That is not all", he added, "for there are communities in time as well as in space, and the most original minds, in some sense isolated in all contemporary groupings, find their true affinities in continuing the sequence of their predecessors, and their fulfilment only in their successors".

In this concluding part of his address, Sir Cyril had been discussing the role of the scientific society in the world of to-day, and more especially its bearing on the relation of the individual to the community. The great movements of thought, he pointed out, and even the lesser ones of whim and fashion, spread from leaders, and only minorities in general exercise an independent taste and judgment or produce original thought. The propagation of an idea demands the right conjunction of unknown human factors, but even when these are propitious nothing will initiate the change save the operation of a minority small enough to defy statistical calculations.

While the majority and the minority are thus generally mutually dependent, in scientific investigations the lavish material ways and means needed, particularly the further knowledge advances, make the individual in isolation, except under rare conditions, correspondingly impotent. The community as a social and political whole cannot be expected, however, to possess the detailed understanding to support him, and with the tremendous issues at stake to-day, it is necessary to create, to mediate between the individual and the major group, a specialized minor community, large enough to command prestige and confidence, but with membership limited to those who put the claims of knowledge first. This is the part that the scientific society and academy, rather than some government institution or the universities, have to play, and Sir Cyril sees them as providing several vital things that neither government nor industry can provide so well. Sir Cyril instances non-commercial periodicals for the publication of discoveries, a measure of financial support for ideas still too embryonic to be of immediately obvious practical application, the mutual stimulus of association and discussion and the immaterial reward of honour for intellectual achievements.

If an academy maintains high standards of unquestioned impartiality, it sets the tone throughout the scientific community and exerts its influence far beyond the confines of the learned world. When the

closest connexions with government organizations or industry are maintained, the professional men of science hear of the needs of the State and of industry, and these in their turn are irrigated by the currents of scientific thought. The process of communication of ideas, Sir Cyril rightly stressed, is not something purely mechanical but rather a sensitive nervous mechanism endowing the community which possesses it with capacities and potentialities realizable in no other way. The subtle co-ordinating action of an academy, he pointed out, can no more be replaced by a bureaucratic organization or a system of economic incentives and deterrents than the intricately evolved biological controls of a living organism can be replaced by widely devised mechanical appliances.

Sir Cyril Hinshelwood's remarks deserve to be deeply pondered by scientists and technologists both in relation to the scientific society and to the professional association. It is clear that both have a part to play in establishing the most effective conditions of communication and for the functioning of creative thought and work, and perhaps more especially in respect to the professional association. It is almost a generation since A. M. Carr-Saunders and P. A. Wilson published their study of the professions, and apart from the many changes in the organization of the professions, the time is ripe for a further critical examination of the functions of the professional, as well as of the scientific and learned, society in the world of to-day, and Sir Cyril's address challenges the creative thinking that is required. His comments indicate very clearly that the failure of some professional organizations to take clear decisions about individual and corporate membership may well prejudice the effectiveness with which they can serve the community as a whole.

The mutual stimulus of association and discussion is not, however, limited to the scientific society or academy as such. It can equally be carried out by a body in which the scientist and the non-scientist are brought together, as in the Manchester Literary and Philosophical Society, and in respect of promoting public understanding and creating the awareness of what is needed to support scientific activity, it may sometimes function more effectively than the purely scientific society. That Society has moved to its new buildings on the site of the premises which were destroyed by bombing in December 1940, in the hope that it may be a meeting place for people in Manchester who are interested in different aspects of the arts, science, commerce and industry. Quite apart from the fact that its own membership offers possibilities of wider contacts than the University itself could hope to provide even if not departmentalized, other societies in the city are already

arranging to use the new premises for their meetings, and there is some reason to hope the Society and its buildings may once again become the centre of Manchester's intellectual life.

Whether in the specialized scientific society or academy or in the more general society as exemplified by the Manchester Literary and Philosophical Society, this question of communication is all-important. What is needed above all is ease of communication across not merely the departments or disciplines of particular branches of science both within a university or academy and between the sciences generally and other fields of human endeavour. In addressing the Manchester Society, when he formally opened its new premises in September, Sir Cyril did not return to his earlier theme of the specific role of the learned society in the world of to-day, but he boldly challenged as artificial some of the distinctions between the arts and the sciences. He did not entirely accept as valid Sir Charles Snow's picture of the two cultures, and much that he said was not simply an eloquent plea to abolish some of the conventional distinctions between the arts and the sciences and to concentrate rather on what they had in common, but was a major contribution to the debate on general education and the education of the scientist in particular which had been a feature of the recent meeting of the British Association at Cardiff.

Prof. A. H. Cottrell, however, in a talk "Scientists: Solo or Concerted?" broadcast in the Third Programme and printed in *The Listener* of September 15, dealt more specifically with this theme of the individual or the creative minority and the relation of individual or minority to the majority of the community in which they live, from which Sir Cyril Hinshelwood had originally approached the question of the scientific academy. Emphasizing how misleading can be the popular image of the solitary scientist withdrawn from the world, Prof. Cottrell pointed out that the scientist, however remote he may seem, is always bound closely to the scientific life around him. He cannot work in a vacuum, but has to take the ideas and problems as they exist among his fellows, transmute them in his own personal way and then bring them back as offerings to the community.

Prof. Cottrell's analysis of the way science advances is worth considering from this point of view of the function of the scientific or learned society. All scientists and technologists, he points out, are users of what has gone before them. At any instance there is a narrow frontier dividing what has gone before from the problems still to be solved, and while this frontier is occasionally stationary where it runs up against one of the big problems of science, for the most part it is steadily moving forward; and keeping in touch with its position from day to day, even on a narrow sector, has become surprisingly difficult. In Prof. Cottrell's view, it is the main problem that the modern scientist has to face in his own work, and finding it exactly is half the battle in modern research. If the scientist does not find it, he is in danger either

of being too timid and wasting his talents on a stale problem or of being too bold and futilely attempting the impossible. If, however, he can pin-point its position really well, deciding the next step forward and how to make it is often surprisingly easy.

Prof. Cottrell's own deduction from the effect of this principle on the pattern of scientific research itself, and the consequent emphasis on meeting as many people working in your own field as possible and meeting them as often as possible, is that where this cannot be done every day in a great laboratory, the need should be met in a scientific conference. His emphasis, moreover, is on the informal contacts and discussions at such conferences, when proceedings in any event are often very belatedly imperfectly reported, and his address lends no support to any proposal for elaborate mechanical means of indexing or recording their proceedings. He recognizes, in fact, that the real value of such conferences is derived from personal participation, and nothing can replace this.

Here, like Sir Cyril Hinshelwood, Prof. Cottrell is emphasizing the dependence of creative work on human qualities—boldness, conservatism, originality—that run through the fabric of all human endeavours, and to his mind the big projects and great laboratories are gradually leading to a new kind of creativity in science. By pooling their individual talents and efforts in a common purpose the members of such organizations are able to attempt new ventures with a boldness and on a scale far beyond the scope of the individual, and he compares the work of many modern laboratories in science with the collective creativity involved in the production of an opera or ballet. In some parts of science it has, of course, not yet become necessary to work in these large groups, but even so, the large laboratory offers advantages in keeping in touch with the frontier and in the stimulating company of one's colleagues. In nuclear physics, however, in radio astronomy, nuclear energy and aeronautical research, the equipment is so large and costly that there is no alternative.

Here again, Prof. Cottrell's thought seems to run with that of Sir Cyril's, and he suggests, indeed, that the arts have something to teach science in the organization of large-scale scientific research and how best to encourage the delicate but all-important balance between individual creative research and collective team-work. There are questions here of education on which Prof. Cottrell just touches, but it should be clear from his remarks how important a part the scientific society or academy has to play in the advancement of modern science. It will not indeed eliminate the need for the scientific conference, particularly at the international level, and it can play a useful part in promoting the organization of such conferences where required. Its real work, however, lies in the fostering of regular and easy and informal contacts and discussions, not simply between specialists, but across the different disciplines. Moreover, Sir Cyril Hinshelwood and Prof. Cottrell agree in recognizing the value of such contacts and discussions not merely within the

sciences but also across the boundaries of science and the arts. Societies like the Manchester Literary and Philosophical Society which seek to bring the scientist into closer and regular touch with those who work in different fields of art may well have a large contribution to make in stimulating creative thought and the new studies which are required to solve some of the major problems of the organization and administration of science itself, quite apart from the value of such contacts stimulating a fresh approach to some problems of science itself. Moreover, such societies assuredly have their part to play in the task of public education, of promoting the general understanding of the nature of science and the way it works and advances, that become more and more essential as the demands of science on the public purse extend.

For all such reasons it is to be hoped that the Literary and Philosophical Society in Manchester and kindred societies throughout Britain and elsewhere, no less than learned, scientific and professional societies generally, will respond to Sir Cyril's challenge to the Manchester Society and grasp their opportunities with boldness, with vision and with imagination.

EDMUND HUSSERL: 1859-1959

Edmund Husserl 1859-1959

Recueil Commémoratif publié à l'Occasion du Centenaire de la Naissance du Philosophe. (*Phänomenologia*, Vol. 4.) Pp. xi + 306. (La Haye: Martinus Nijhoff, 1959.) 20 guilders.

THE year 1859 in which Edmund Husserl was born was indeed a landmark in the progress of European learning. It claimed also John Dewey, Samuel Alexander and Henry Bergson. As if that were not enough, in that same year Darwin's "Origin of Species" and Marx's "Critique" made their appearance. The passage of time was in fact to show that Husserl and Alexander both died in 1938. The present volume, beautifully printed and set out, was issued as a centenary collection in honour of the master of phenomenology. The twenty-five contributors, as one would expect, are leaders and critics in that branch of philosophy, and they write, for the most part, in their own languages, namely, English, French, German and Italian. Yet these pages are a typically 'overseas' assemblage; not one of the distinguished authors comes from Great Britain. In his lifetime particularly, Husserl's force was a Continental radiation having as it were secondary foci in the United States which have sharpened with the years and yielded him praise. But, nearer home, anyone who has visited the Archives at Louvain will read Prof. van Breda's paper in this book with particular pleasure. It is outstanding for its scholarship, sympathy and charity. Possibly not too well known is the fact that the savants there assumed the responsibility not only of safe custody, but also the task of transcribing (from Husserl's shorthand) and editing the mass of material which the late Frau Husserl had been able to deliver into their hands, and thus to save from the ravages of Hitler's *Reich*. As Prof. van Breda modestly remarks, Germany has

gained a little intellectual territory in the process, a scholar's embassy on Belgian soil.

But this is only the result of something that was afoot some sixty-odd years ago. Husserl's mental strife was intense: he was able (and this was the operative part of the performance) to share it with his students, and literally to compel them to labour too. Stiff and formal—not unlike Max Planck—in his university lecturing, he was creative to a high degree in his seminars. All this was to one purpose, to obtain the greatest possible rigour (in theory, a pre-suppositionless philosophy), and to ask the right questions. Husserl was an artist in the shades of meaning, and his small audiences instinctively sensed his deft use of word and phrase. Of course, such a professor-pupil relationship, almost medieval in its fervour, would be unthinkable to-day with our crowded class-rooms and tight schedules. This book is worth reading on that score alone, to catch a glimpse of the kind of detachment necessary to become an epistemologist of stature. Husserl was a great enough man to reveal to his hearers much of his own early confusions, and how he escaped from them to do battle with psychologism, that is, the subtle intrusion of psychological elements into purely logical processes. Moreover, it should not be forgotten that he came to mental manhood as a pupil of the great Weierstrass, with a dissertation on the calculus of variations (1882), which apparently was never printed. In the publication now under review the reader is presented with a full bibliography, and a worthy reproduction of the drawing of the master by Rudolf Stumpf.

Husserl's attempt to use phenomenological methods in the sphere of social science was scarcely a success, if judged in relation to any form of transcendental theory of knowledge. But he achieved an advance; if one admits the value of philosophical anthropology as at least a worth-while development of the problems of the living world. Even though much of his work in this direction was contained within the restricted field of 'reduction' or 'bracketing'—corresponding to a suspension of judgment—yet he established a vital principle in his emphasis on the place of the natural attitude. The empirical type of sociology has much to learn from this, more particularly when one recollects how hard Husserl strove to practise what he preached. Those who enjoyed the intimacy of his friendship, and accompanied him on his 'philosophical walks' at Freiburg, must have become convinced that the peripatetic schools of the Golden Age at Athens must surely have come to life again. But Husserl could be very lengthy: it was not uncommon for him to think aloud, without notes of any kind, for a couple of hours on end, an ordeal which his listeners not only survived but even enjoyed. They were there *d'assister* at the birth of ideas, and they had their reward.

An element of paradox seems inseparable from much German thought. It is displayed here in Husserl's scientific philosophy as a free gift to those who would divest any theory of knowledge of its scientific content. He fought against naturalism only to help it on to its feet. In broad outline, Husserl shares with Søren Kierkegaard, Karl Barth, and Rudolf Otto the tendency to stress the 'wholly other'. In England we do not do this: our urge to find a middle way carries us in the opposite direction. Yet there is to-day a movement towards subjectivity, not in the mathematical sciences, but in biological

studies, which may well herald the advent of biophysics as the leading discipline in future experimental philosophy.

The chapters of this admirable book, each one by an acknowledged authority on his own ground, are written to survey a wide field: reminiscent, biographical, epistemological, psychological, and experimental. The late Dr. Alfred Schutz, one of the contributors, met Edmund Husserl many times during the nineteen-thirties in Freiburg, Vienna, or Prague, and sums up the impression that was universal, when the name of the master of phenomenology was mentioned, in just two words, "*Ecce philosophus*".

F. I. G. RAWLINS

PRODUCTION AND PROCESSING OF URANIUM

Uranium Production Technology

Edited by C. D. Harrington and A. E. Ruehle. Pp. xii + 579. (Princeton, N.J., and London: D. Van Nostrand Company, Inc., 1959.) 131s. 6d. net.

THIS book is the first comprehensive compilation of the technology of uranium production. The material for the book was prepared by the technical personnel of the Uranium Division of Mallinckrodt Chemical Works, under the direction and guidance of the United States Atomic Energy Commission's Division of Information Services. The Commission recently declassified virtually all the significant features of the technology, thus making possible the publication of the book.

For the benefit of the industrial chemist, the production of pure uranium from the ore concentrate is described in considerable detail both in regard to the plant and to the chemistry of the processes involved. Plant for both batch and continuous processes is described, and the accounts of advanced methods, such as ion exchange and fluidized bed techniques for the manufacture of both uranium tetrafluoride and hexafluoride, are of special interest. It is apparent that very little information has been withheld, and cost figures for many of the processes are included.

For the metallurgist and the engineer there are excellent chapters dealing with the vacuum casting and subsequent forming of the uranium metal, and again considerable detail of the plant is given.

Chapter 10 is worthy of special mention and deals with the physical metallurgy of uranium related directly to the problems of metal production and fabrication. The structure in terms of the allotropic forms of uranium, the response to heat treatment and the degree to which the grain size may be controlled are all discussed. Lists of the usual mechanical properties, showing the effect of temperature, are given, and the final section reviews mechanisms of alloy formation and shows the effects of additions on the physical properties, structure and mechanical properties. The photomicrographs showing the structure of uranium and of typical inclusions are particularly useful.

British experience of fabricating uranium metal by methods other than casting and machining is relatively limited. The next three chapters, dealing with forging, extrusion and rolling, might therefore have been expected to be of especial interest. In fact they

are just a little disappointing—particularly that on extrusion—and it is difficult to believe that we are being given an adequate account of the fairly extensive body of American knowledge on these aspects. An additional chapter on fabricating high-uranium alloys gives some useful basic data; this chapter also has a very good bibliography.

The final chapter is devoted to health hazard control and gives an extensive review of this particularly important aspect of uranium processing. Shielding against beta and gamma radiation is described, and useful guidance on the methods available for dust control is given.

Few criticisms can be made of the book, and these are mainly minor ones. Its pages include a wealth of information on uranium production and processing. Extensive use is made of diagrams and photographs, and there are 750 references. The book will be invaluable to all those interested in the manufacturing processes of uranium and its compounds.

D. E. R. HUGHES

GENERAL ASTROPHYSICS

Astrophysique Générale

Par J. C. Pecker et Prof. E. Schatzman. Pp. x + 756. (Paris: Masson et Cie., 1959.) Broché, 12,000 francs; cartonné toile, 13,000 francs.

ASTROPHYSICS is not a big subject in relation to some other sciences, but in my view the day has passed when any complete and satisfactory account of it can be compressed into one text-book, unless at a quite elementary level. Here two well-known French astrophysicists have attempted heroically to do the well-nigh impossible, and even if the result falls short of perfection it deserves a warm welcome, for good general text-books in this field are very scarce. We have on one hand a fair number of specialist monographs, some of them invaluable, and on the other more than enough glossy semi-popular and popular books, most of which should be avoided as the plague by any serious student. Between these extremes there is remarkably little.

The first 100 pages of "Astrophysique Générale" are given over to a summary of "what every young astrophysicist should know"—everything from hydrodynamics to Hamiltonians, statistics to spectroscopy. It illustrates the wide range of technical knowledge a theoretical astrophysicist ideally should command, but is much too compressed to be anything but a refresher course for a recent honours graduate in mathematics or physics. A whole book written along these lines would be very useful, but I question the wisdom of attempting the task in less than, say, 1,000 pages. Part 2, dealing with astronomical instruments and methods of observation, is at a very different level of sophistication. It shows signs of having been written by theorists, for there are a number of over-simplified or over-optimistic statements (for example, "Pour les étoiles jaunes et rouges, la mesure des magnitudes radiométrique permet d'obtenir aisément les magnitudes bolométriques"), as well as a few small errors. In Part 3, the longest in the book, the authors are, however, more on their own ground, discussing what we know of stars, their spectra, masses, intrinsic luminosities, radii, and the theories of their atmospheres and their interiors.

Part 4 deals with systems of stars, the structure of the Milky Way and of external galaxies. It also has chapters on stellar dynamics, interstellar matter and stellar evolution. Part 5 summarizes our knowledge of the Sun, which is regarded as a typical G2V star, and of the planets and other bodies in the solar system.

This is not a book for a beginner. The reader needs a solid background of mathematical physics and at least some prior acquaintance with elementary astronomy. There is a real need for astrophysical text-books at this level; but this one, it seems to me, attempts to do too much in too little space and one result is that in places it tends to be scrappy. I suspect that quite competent students, especially perhaps the more conscientious and thoughtful, might sometimes find its pace slightly bewildering.

The production is on the whole good. Too small a type for comfort has sometimes been used in subscripts, etc. The illustrations are in general good, but a few are misleading. A certain number of misprints need correction. R. O. REDMAN

PROGRESS IN THE FLORA OF CANADA

Flora of Alberta

A Manual of Flowering Plants, Conifers, Ferns and Fern Allies found growing without Cultivation in the Province of Alberta, Canada. By Prof. E. H. Moss. Pp. v + 546. (Toronto: University of Toronto Press; London: Oxford University Press, 1959.) 80s. net.

DESPITE some 250 institutional herbaria, and some 25 journals which regularly publish taxonomic papers, in temperate North America, our broad knowledge of the flora of that continent is surprisingly fragmentary. There are large areas of the continent and large numbers of taxa which, by modern standards, have not been critically, or even adequately, examined. This should not be taken to imply that large numbers of 'new' species remain to be found in North America—for the country has generally been well explored, even if not yet thoroughly collected. Rather, it indicates the large amount of work that is yet to be done before we have even a bare catalogue which will show the extent of the North American flora.

Until very recently, the flora of Canada has been particularly poorly understood. The most southeasterly part of Canada has been treated in the two standard Floras of the north-eastern United States. Southern parts of the prairie provinces were included in the now somewhat outdated Floras of the prairies and plains, and of the Rocky Mountains of the United States. Southern British Columbia has a Flora published as long ago as 1915 (with a Supplement published in 1947). In the past twenty years, however, the botanists of the National Museum of Canada have made a concerted attack on the flora, with the view, eventually, of a proper "Flora of Canada".

The regional Floras of the National Museum of Canada, combined with Hulten's monumental "Flora of Alaska and the Yukon" (1941-50), Polunin's "Circum Polar Arctic Flora" (1959), and the various more generalized publications of the Canadian Department of Agriculture are now beginning to give us a rather good idea of the outlines of the Canadian

flora. The most serious gap in our knowledge, of recent years, has been the lack of a Flora for the western prairies and the Rocky Mountains. The publication, by the University of Toronto Press, of the "Flora of Alberta", written by the distinguished Canadian botanist, Prof. E. H. Moss, is, then, an event of some considerable interest and importance.

The Province of Alberta is one of the twelve administrative divisions of the Dominion of Canada. It extends (with irregularities in the south-western corner) from the 110th degree of west longitude to the 120th degree, and from the United States boundary at 49 degrees of north latitude northwards to 60 degrees. It has an area of about 255,285 square miles. The flora, as herein enumerated, consists of some 1,605 species of vascular plants. These are the bare facts of the matter.

After some 200 years of experiment and practice, it is fairly clear to botanists what the essential qualities of a good Flora are. A Flora (as distinguished from the flora) is, first and foremost, a tool for the identification of any plant included within its circumscription of areal and systematic range. Basically, the most important part of the treatment is the delimitation and description of the individual taxa. These circumscriptions should be clear, precise, and as brief as possible. Supplemental data, such as descriptions of habitat, flower colour, and season of flowering are frequently of considerable practical usefulness.

For the general user, however, the most important parts of a Flora are the 'keys'—analytical tables of pairs of contrasting characters, set out in a conventionalized form, by which one should be able to be led, through the sets of alternatives, to the name and description for the taxon of which the user has a representative in hand. Indeed, many very useful Floras consist, essentially, of keys alone. To be useful, a key must be infallible. Infallible is a strong word—but if the taxonomy of the text is an accurate reflexion of the facts (plants) found in Nature, infallibility is practically possible. The large number of practically infallible keys in Floras and monographs which are in general use is sufficient proof of this statement. Keys which do not work very frequently indicate taxa which are not adequately understood.

The "Flora of Alberta" is an extremely valuable tool, which should have considerable usefulness both in the herbarium and in the field. It is obviously based on the author's first-hand knowledge of the Province. The descriptions are generally clear and concise. The keys to the families and to the genera seem to be rather good examples of their kind. The keys to the species are occasionally a little less happy, especially when qualitative, rather than quantitative, characters are relied on too heavily (*Salix* and *Senecio* afford examples of this).

The "Flora of Alberta" is, as the author comments in his preface, "a pioneer effort". As a pioneer effort we are grateful that the work has been done. It is no adverse reflexion on the work of the author if we suggest ways that future editions might be improved. I think that we would like to see a few pages devoted to a discussion of the vegetation, the geography, and the geology of the Province. A map of the area would be helpful. Illustrations of some of the more interesting taxa would be useful. A short discussion of the history of botanical exploration in the Province would also be of interest, and would add a welcome perspec-

tive. Notes of flower colour and season of flowering would enhance the usefulness of the Flora to the layman.

It is very easy for those of us who have been brought up in regions that are well known botanically to pick flaws in a pioneer work covering an area that is little known. We should remember, when we are tempted to criticize, the very great debt we owe to men like Prof. Moss (need we mention Ridley, Asa Gray, or J. D. Hooker), who, in their retirement, have not been content to rest, but have, instead, given us basic works to build on. Their errors may or may not be glaring. They, not we, have done the work.

GORDON P. DEWOLF, JUN.

THE CHEMISTRY OF AIR POLLUTION

The Chemical Analysis of Air Pollutants

By Dr. Morris B. Jacobs. (Chemical Analysis: a Series of Monographs on Analytical Chemistry and Its Applications, Vol. 10.) Pp. xviii+430. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1960.) 102s.

ONE need not be a chemist to appreciate the ever-growing menace of air pollution in urban communities. Too often the discomforts and dangers of the winter 'smog' descend on a choking populace, apparently powerless to alleviate the distress caused by its own machinations. This is pollution at its obvious worst, but there are many other forms of pollution which though less conspicuous are no less hazardous and indeed, in the case of radioactive contamination, can have such far-reaching effects that the entire populace of an affected area must be evacuated.

In order to control air pollution, it is first necessary to measure it, and this involves the determination of the nature and amount of the contaminating materials. In this book, Dr. Jacobs, who is a well-known consultant in this field, sets out his systematic approach to the many chemical and physical problems involved in analysis of gaseous and particulate contaminants in air.

Chapter 1 contains a general account of sampling and the available means of taking samples for analysis. Chapter 2 is devoted to the measurement of volume, quantity, and velocity of gases. Chapter 3 considers sootfall and dustfall, and the analysis of soots and dusts by a number of standard methods. Chapter 4 deals with the evaluation of atmospheric dust, particularly the particle sizes involved. Chapter 5, on suspended particulate matter, gives procedures for the chemical analysis of organic and inorganic constituents. Chapters 6 and 7 deal respectively with smoke density and smoke shade, and the sampling and analysis of industrial stack-smoke. Chapters 8 and 9 cover the chemical analysis of sulphur and halogen-containing air pollutants, Chapter 10, that of nitrogenous compounds and ozone, Chapter 11, oxides of carbon, cyanide, and phosgene, and Chapter 12, general organic compounds. In Chapter 12 these materials are arranged according to their functional groupings. Chapter 13 covers the determination of radioactivity and the detection and determination of hazardous isotopes such as strontium-90. The analysis of incinerator-flue gases and motor-vehicle exhaust gases is dealt with in Chapters 14 and

15. Chapter 16 deals with the interesting subject of 'odour' analysis, which involves the determination of the amount of a (generally) malodorous material in the atmosphere. The final chapter (18) describes instruments used to monitor particular types of air contaminants. An appendix contains a number of useful tables and data pertinent to the information given in the text.

The wealth of information given in this book and the concise and systematic way in which it is presented must make it an obvious choice for all who are interested in the control of air pollution. Its use is not restricted in any way by its contents which are directed primarily to the analyst, but are of interest to a much wider section of the community, such as engineers, factory inspectors, public health and sanitation officers. Much of the analytical chemistry can be adapted for courses in colleges and universities, and the inclusion of many simple and inexpensive methods is of great value not only to teaching institutes, but also to the many communities and industrial organizations which do not have the funds necessary to set up the more elaborate methods and instrumental techniques.

For the analytical chemist, this book provides an admirable addition to the literature on applied analysis. It maintains the high standard of its predecessors in the Interscience series of Monographs on Analytical Chemistry and its Applications, and it must undoubtedly become a standard work on the subject of air pollution.

W. I. STEPHEN

VEGETABLE PATHOLOGY

Vegetable Diseases and Their Control

By Prof. Charles Chupp and Prof. Arden F. Sherf. Pp. v+693. (New York: The Ronald Press Company, 1960.) 12 dollars.

ALTHOUGH directed primarily at the American reader this publication should prove of interest to those in Great Britain and elsewhere.

After preliminary sections on seedling diseases and those affecting a range of host plants, there are sixteen chapters each dealing with the diseases of a group of vegetables. Potatoes are not included. The book concludes with chapters on minor element deficiencies, nematodes and soil sterilization. A valuable feature is the mention of varieties that show resistance to the various diseases.

As indicated in the preface to the volume, an attempt has been made to write in as nearly a non-technical manner as possible so that the book may be of use to the amateur as well as to the commercial grower. Considerable success has been achieved in this respect and the narrative style is very readable, a feature which is assisted by the excellent clear type. The sections abound in practical recommendations for control and obviously contain the fruits of many years experience in this field.

The book is also intended to serve as a text for students, research specialists and advisers, but its value in this respect is less apparent. There are few sub-headings within the sections on each disease; with a few minor exceptions there are no drawings or photographs of the causal organisms, and little or no mention is made in the text of the references quoted at the end of each section. These therefore

lose much of their value and they may also be criticized on the grounds of incompleteness. The work and monograph of Colhoun on clubroot of crucifers, for example, receive no mention, and the chapter on soil sterilization is accorded five very meagre references (this has since been found to be due to the printers omitting in some copies a page of references).

Some of the control measures now seem rather old-fashioned (for example, soaking seeds in copper sulphate solution to control certain damping-off diseases). Errors also occur in several places. The photograph of the effect of *Verticillium* wilt on tomato leaves is not of the normal symptoms associated with the disease; Bordeaux mixture is not used (as stated) against *Didymella* stem-rot of tomatoes; the section on big vein of lettuce does not give an accurate representation of the latest information or experiments on the disease.

The publication gives the impression that in attempting to cover a very wide range of subjects and of readers the authors have only partially succeeded. Even so, the book does provide a useful compendium which may with advantage be used both as a guide to some of the other sources of information on the subject and as a supplement to them.

W. G. KEYWORTH

KNOWING OURSELVES

Understanding Human Society

By Prof. Walter Goldschmidt. (International Library of Sociology and Social Reconstruction.) Pp. 253. (London: Routledge and Kegan Paul, Ltd., 1959.) 21s. net.

THE distinguished editor of the *American Anthropologist*, Walter Goldschmidt, has essayed a most difficult task—to provide a guide to the development of man in society. Such a book has long been needed. The great majority of anthropologists have for too long been too preoccupied with the immediate problems of their subject. There can be little doubt that studies of kinship have dominated the anthropological horizon for a considerable time. It is refreshing, therefore, to come upon a book which attempts to deal with the broader implications of the subject.

One of the most valuable sections of this book is entitled "The Dimensions of Anthropological Theory". It begins, "The ultimate task of the anthropological enterprise is to explain the uniformities and diversities in the natural condition of mankind . . .", and proceeds to a discussion of the various approaches which have been made to the study of man. Curiously enough, the history of anthropology, with the exception of Haddon and Pennman, is extraordinarily sparse. For the student this chapter fills a long-felt want. The teacher is apt to presume a knowledge on the part of the student which does not always exist. Frequently he is too concerned with his own bias to worry about the theories of others. The individual who sat at the feet of the late Father Schmidt in Vienna would scarcely have obtained an unbiased account of, say, Malinowskian functionalism. Prof. Goldschmidt, on the other hand, is remarkably fair in his treatment of the theories of others.

In developing his theory of social evolution, which forms the core of the book, the author is at pains to point out that we must exclude any idea of moral values which so bedevilled the old evolutionary

hypotheses. The theory presented is eminently respectable, and few would quarrel with it. Its fault lies in the fact that it does not take us very much further on the way. "It does not in and of itself explain these social systems, in the sense that it offers a full account of what makes them as they are." Perhaps no theory could; but we are back where we started being forced to consider each society as a unique whole.

The value of this book is perhaps not in the field of original theory but rather in the clarity and succinctness with which the author deals with the ideas of others about the nature of human society. In the jargon-ridden jungle of the social sciences, Prof. Goldschmidt has created a little oasis of simplicity for which we must be grateful. It must be admitted that Americans are not usually exemplars in this matter.

The publishers have not been too well served by the printers who, by using a different type for the concluding words or sentences of chapters, have managed to convey an arcane sense which is totally misleading.

F. HENRIQUES

SOCIOLOGY OF CASTE IN CENTRAL INDIA

Caste and Kinship in Central India

A Village and its Region. By Adrian C. Mayer. (International Library of Sociology and Social Reconstruction.) Pp. xvi+295+16 plates. (London: Routledge and Kegan Paul, Ltd., 1960.) 35s. net.

THIS is a sociological study of caste as it operates in Central India in the E. M. Forster country, and it provides a valuable addition to the literature on caste in India. Much has been written on this subject, but mainly on a broad and generalizing and on an India-wide scale, or in a theoretical, evolutionary or historic form. What are lacking are the detailed studies of caste as it actually functions in specific Indian communities, against which these generalizations and hypotheses can be tested. Dr. Mayer's book is one of the best studies of this sort that has yet been made and the only one that deals with the caste system as it operates in a multicastrate village and its surrounding neighbourhood. It brings out very clearly the interconnexion between kinship, sub-caste and caste. Village boundaries are shown to be something more than territorial and to mark the difference between two kinds of relationship, that of common caste and of agnatic kinship (in the village) and that of common sub-caste and of bilateral and affinal kinship (in the region).

The book is divided into three parts: the first sketches the historic and economic background, the second examines intercaste relations as they affect ritual, economic and political status and the third analyses the constitution of the caste, its internal structure, the part played by unilinear descent, and the pattern of marriage and of social control within the sub-caste.

Social anthropologists interested in kinship, whether or not they are also concerned with the study of caste, will find much of value in this study, while those more immediately concerned with rural Indian political and economic development would do well to read the chapters on caste and village leadership and on the economic aspects of caste.

G. I. JONES

Advances In Applied Mechanics

Vol. 6. Edited by H. L. Dryden, Th. von Kármán, and G. Kuerti. Pp. x+294. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1960.) 9 dollars.

THIS latest volume of the series is concerned entirely with fluid mechanics. There are two chapters on boundary layers: one on unsteady layers, by K. Stewartson; the other on layers in a dissociated and ionized gas, by G. Ludwig and M. Heil. The two following chapters are on high-speed flow: the first on shock propagation along varying ducts, by W. Chester; the second, a particularly valuable account of similarity and equivalence, by K. Oswatitsch. The last chapter, a short one by R. Wille, is on Kármán vortex streets.

Reading through this latest collection of essays on topics in applied mechanics, one is made to realize once again what a remarkably sound idea the publication of this series of volumes has been. To the expert who has already formed his own balanced view of a subject, an individual essay may not always seem worth while; partly because, no doubt, he disagrees with the view taken by the author, and partly because there is not usually much original material to compensate for other shortcomings. But to the newcomer, whether he be a complete novice or a more experienced person broadening his interests, the publication of a detailed and up-to-date account of a subject, representing the personal view of someone who has usually taken an active part in developing it, is a valuable service—much more valuable than the publication of the few summarizing paragraphs, followed by several hundred references, that sometimes pass for a review. The editors, no less than the latest additions to the list of authors, are to be congratulated for maintaining this service.

IAN PROUDMAN

Viscoelasticity

Phenomenological Aspects. Edited by J. T. Bergen. (Symposium sponsored by the Armstrong Cork Co., held at its Research and Development Center, Lancaster, Pennsylvania.) Pp. x+150. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1960.) 6 dollars.

SOME explanation is required concerning the definition of terms in the title of this book. "Phenomenological aspects" are clearly defined as those concerned with the material "as a continuum which is characterized by specific, fundamental parameters"; as opposed to aspects "dealing with molecular structural or molecular model considerations". Viscoelasticity is taken to include behaviour involving flow, more often currently described as elastico-viscous. Both linear and non-linear relations are discussed but there is some confusion over the definition of "linear". One contributor gives alternative definitions implied to be synonymous (p. 28), although it is quite possible to find materials (for example, those obeying Bach's equation) the behaviour of which would be linear according to one version of the definition but non-linear following the other.

With some exceptions, the equations developed in these essays are applied by the authors to large masses of data from work published elsewhere, usually on materials which can be tested over wide ranges of stress and many decades of time. Only a few types of test are feasible under such conditions and it is remarkable that sufficient superposability

exists to make possible so good a measure of agreement as has been found.

The book is important in correcting a tendency, prevalent in certain quarters, to believe that the only meaningful approach to rheology is through molecular considerations. It is a pity that one or two of the essays are written in such bad English, as judged by either British or American criteria, as to be irritating to the reader.

G. W. SCOTT BLAIR

Organic Chemistry

By Dr. I. L. Finar. Vol. 2: Stereochemistry and the Chemistry of Natural Products. Second edition. Pp. xi+834. (London: Longmans, Green and Co., Ltd., 1959.) 45s. net.

THE second edition of Vol. 2 of Finar's "Organic Chemistry" matches the high class of the third edition of Vol. 1. These new editions were both published in 1959. They are designed to provide a foundation for the organic syllabus of a special honours degree course in chemistry; this objective has been achieved. Present authors of text-books suitable for this level have to concern themselves with deciding what can be left out, and Finar's selection has obviously been made carefully. He has included practically all those topics of fundamental importance, but some quite recent developments are also introduced in such a way that the interest of the reader is excited. A valuable feature is the comprehensive list of reviews and monographs given with each chapter.

The discussion of stereochemistry occupies 210 pages. It is clear and covers optical and geometrical isomerism, the stereochemistry of the diphenyls and the stereochemistry of elements other than carbon. This is balanced by an introduction to more recent developments such as the stereoelectronic features of chemical change and conformational analysis.

The major part of the book is devoted to the determination of the structure and the synthesis of the more important classes of natural products. These have been carefully selected and include carbohydrates, steroids, amino-acids, proteins, alkaloids, anthocyanins, nucleic acids, porphyrins, vitamins and antibiotics. This is the best treatment of these topics which is easily available to undergraduates. There are certain gaps in the coverage provided by Vols. 1 and 2 of this work, but this is inevitable. The books are easily read, and this is a pleasant change from those which are just catalogues of structures and reactions. The second edition of Vol. 2 is a better book than the first edition and can be warmly recommended.

W. D. OLLIS

Scientific Manpower

By Joyce Alexander. Pp. viii+135. (London: Hilger and Watts, Ltd., 1959.) 15s. net.

WHAT factors determine whether a young person does or does not become a scientist? This is the question which Mrs. Alexander examines in this carefully documented essay. She points to the shortage of scientific man-power; she examines the educational system which has failed to overcome the shortage; and she discusses the proposals which have been made to overhaul the educational system and to equip it to serve contemporary needs. There is a very sensible chapter on scientific woman-power. This is a neat and useful little book. It does not break fresh ground, but it equips the reader to do some thinking for himself.

RECENT RE-ENTRY RESEARCH AND THE COSMIC ORIGIN OF TEKTITES

By DEAN R. CHAPMAN

National Aeronautics and Space Administration, Ames Research Center, Moffett Field, California

OPPOSING views have been expressed in recent years as to whether tektites are terrestrial or cosmic in origin¹⁻⁵. The purpose of this article is to outline some new results obtained by bringing to bear on the problem recent advances from the discipline of re-entry aerodynamics. It is concluded that the australite tektites show sufficiently clear and diverse indications of atmospheric entry to enable their approximate initial velocity and flight path angle to be determined. A surprisingly narrow band of entry velocity is delineated which is in the cosmic-origin range, and, more intriguing, in that particular range uniquely compatible with origin from the Moon.

Although the present work is restricted to australite tektites, this does not limit the generality of the end result. The various tektite groups unmistakably are related by a family-like chemical composition and internal structure; hence, the determination of cosmic versus terrestrial origin for one group also applies to the other tektite groups within the family.

Australite Entry Aerodynamics

It has long been known that australites have been twice melted, and that the second melting occurred superficially on the front surface only. From this and other evidence, Baker¹ has concluded that the australites entered the atmosphere as cold, independent bodies, most of which neither tumbled nor rotated during ablation. Recent re-entry research provides three additional lines of evidence crystallizing this conclusion. During an experimental study in 1959, D. R. Chapman and H. K. Larson (at the Ames Research Center) found that the ablation of glass bodies commonly proceeds through the formation of ring waves being propagated radially away from the stagnation point; strikingly similar waves of 'flow ridges' are exhibited on many australites¹ and on a few javites⁶. A second line of evidence concerns the displacement of a glass particle within an ablation layer. Within the thin, receding, melted layer, the particle displacement near a stagnation point varies essentially exponentially with depth below the surface, and essentially linearly with radial distance from the stagnation point⁷; these same two types of mathematical variation were found in photographic enlargements of the australite thin section *B* in plate *X* of Baker's monograph¹. The third line of evidence arises from a study of australite shapes. At least 98 per cent represent stable aerodynamic configurations in hypersonic flight when orientated in the unique manner that is compatible with the orientation demanded by the directions along which the secondary melt has flowed on their surfaces. Without going into the aerodynamic details, it is noted that such general aerodynamic stability is to be expected only in descent through the atmosphere, and not in ascent⁷. The overall evidence leaves no doubt that aero-

dynamic heating during entry into the atmosphere has been responsible for the second period of australite melting.

Even an absolute proof that an object has entered the atmosphere and suffered ablation at hypersonic velocity does not prove that it is cosmic in origin. The particular numerical value of the hypersonic velocity is of crucial importance. All that has been said about australite entry aerodynamics would apply, for example, equally well for 6 km./sec. entry velocity as for 12 km./sec. Yet, entry at 6 km./sec. could only be from a terrestrial source, whereas 12 km./sec. could only be from a cosmic source (since the Earth escape velocity of 11.2 km./sec. lies in between). Consequently, the aerodynamic evidence for tektite origin hinges on the magnitude of the velocity.

Only through relatively recent developments in re-entry research has it been possible to determine the entry velocity of the australites. Knowledge was required of the rate of aerodynamic heating as developed recently through both theory⁸ and experiment⁹, and of the rate of ablation of silica-rich glass as given by a refined version of the Bethe-Adams theory⁴ recently confirmed in the laboratory¹⁰. In computing trajectories extensive use was made of *Z*-function solutions¹¹ for shallow supercircular entry. Through the use of high-speed digital computing machines the required *Z*-functions were compiled¹².

The analysis also required knowledge of certain physical characteristics of tektite glass, the most important of which is the viscosity-temperature relationship as determined from experiment¹³. Detailed data on the mass, dimensions, and radii of curvature of complete, well-preserved specimens were obtained from Baker's research¹, from additional correspondence with him, and through personal measurement of australites in the British Museum.

Entry Conditions and Geographical Distribution

The limited geographical distribution of a fall provides useful restrictions on the entry velocity. Let us consider first the hypothesis of terrestrial origin, wherein tektites are assumed to result from some violent natural phenomenon which has fused Earth material and thrown the melt far above the atmosphere (far enough to have had time to solidify before re-entering and experiencing the second melting). The exit velocity from the atmosphere would equal the entry velocity; it could not exceed some maximum value and still confine the fall to a limited geographical area. Velocities as high as the orbital velocity of 7.9 km./sec., for example, would spread the fused earth around the globe, and hence are too high to be compatible with a terrestrial origin hypothesis. If the fused earth were hurled in the manner that ejectamenta from hypervelocity impact in stone are hurled¹⁴, then the maximum entry

velocity consistent with a terrestrial origin and confined distribution would be about 6 km./sec. According to the hypothesis of cosmic origin, however, the entry velocity would have to be equal to or greater than 11 km./sec. for direct entry (indirect entry after multiple-pass atmosphere braking¹² is not considered, as it would have resulted in global distribution of a cluster). For cosmic origin, all individual specimens in a tektite cluster would have the same entry velocity.

Results of Analysis

The approximate entry velocity has been determined from: (1) the thickness of the ablation layer near the stagnation point, as given by the displacement of internal glass striæ; (2) the amount of ablation at the stagnation point, as given by the shapes of complete, well-preserved specimens. For each entry angle γ_i (measured relative to local horizontal) the particular entry velocity V_i was calculated which would be compatible with the observed characteristics of a given australite. Entry angles were considered within the range from 90° (vertical entry) down to the overshoot boundary (nearly horizontal entry in which barely enough drag is encountered to land the tektite). In this way a V_i (γ_i) curve is obtained, some point along which the true V_i and γ_i would be located. By computing several independent curves a limited domain of entry conditions is delineated.

Fig. 1

The essential results are illustrated by curves in Fig. 1. Curve 1 corresponds to the entry velocity computed from the displacement of glass striæ in thin section B of plate X of Baker's monograph. Curve 2 corresponds to the velocity computed from the amount of ablation of "perfect button 1212" in Baker's collection. This particular button possesses a complete flange large enough to account for nearly all of the mass melted during entry. It is representative of those buttons which have lost the least amount of mass during entry. Curve 3 corresponds to the same type of calculation as curve 2 only for a large core (Reg. No. 1926-349 in British Museum). This curve is representative of an average large core. Some cores show less ablation and would fall between curves 2 and 3—where most buttons also would fall—while other cores show more ablation and would fall a short distance to the left and above curve 3. All three curves represent specimens found locally in a relatively small area of Victoria. In order for these australites to have entered with essentially a common velocity, this velocity would have to be in the range between about 10 and 13 km./sec.

By invoking certain dynamical limitations, the range of australite entry velocity is narrowed to considerably less than the 10-13 km./sec. band. At the lower end, entry in the 10-11.2 km./sec. range would correspond to terrestrial origin; at the entry angles indicated such velocities would have resulted in world-wide tektite distribution, and hence are rejected. At the upper end, velocities much above 11.2 km./sec. also are rejected, although for entirely different reasons. At 12 km./sec., for example, the required difference in entry angle of between 6° and 17° would correspond—for two specimens falling on the same spot—to impact about an hour apart. Since the approach velocity far from the Earth is 4.4 km./sec. for $V_i = 12$ km./sec., a time-interval of 1 hr. between impacts in Victoria would correspond to a distance interval when far from the Earth of greater than the Earth diameter. It is unreasonable to expect a cluster of such dimensions to land on a confined area of Australia. At entry velocities only slightly greater than the escape velocity (say, V_i of about 11.3 km./sec.) the approach velocity far from the Earth is small, so that the cluster dimensions implied by the indicated differences in entry angle also are small, and thus compatible with the limited area of the australite strewnfield. After imposing such limitations, the only entry velocity range we are left with is the narrow interval a fraction of a km./sec. above the escape velocity. This velocity band is compatible with a lunar origin of the australites. In fact, the Moon is the only known celestial body for which the entry velocity would be expected to be in this particular narrow range.

A note is in order here about the accuracy of the calculations. All equations employed are based on analytical methods that have been verified in the laboratory. However, several physical approximations were employed for simplicity in the computations. For example, in making trajectory calculations the variable mass was approximated by the average before and after entry (specimens were selected which have lost only a small or moderate amount of mass during entry in order to minimize this uncertainty). The estimated accuracy is less than about 2 km./sec. in velocity. Shifts in the various curves of an amount corresponding to the estimated accuracy would not affect the end-result that the

observed features of australites are compatible with a cosmic entry velocity of essentially the Earth escape velocity, and incompatible with the hypothesis of a terrestrial origin.

Among approximately thirty serious hypotheses known to me which have been advanced during the past century in an effort to explain the perplexing origin of tektites, the Moon has had a fair share of supporters, just as have the stars, the Sun, Earth lightning, volcanoes, comets, lost planets, lost Earth satellites, and unknown prehistoric races remarkably advanced in glass technology. In view of this, it seems appropriate to mention the early advocates of a lunar origin. In 1897 Verbeek¹⁵ suggested that volcanic eruptions on the Moon were a possible source of tektites. An alternative mechanism was suggested in 1940 by Nüninger¹⁶, who regarded meteorite impact on the Moon as a probable mechanism for dislodging lunar rock with sufficient velocity to escape the Moon and land on Earth.

Neither lunar volcanic activity nor meteoritic impact on the Moon can be ruled out to-day as being unrelated to tektites. For decades the Moon has been generally regarded as a dead celestial body without remnants of any volcanic activity it may have had in the past. This view has been drastically shaken recently by Kozyrev¹⁷, who obtained spectroscopic evidence of gas escaping from Alphonsus crater in 1958, and of a 1200–1500° K. surface temperature temporarily existing in the same crater in 1959. Inasmuch as lava can bring up material which is lighter and also richer in radioactive elements than the average lunar composition, this provides a simple explanation of why the density of tektites (2.3–2.5) is significantly lower than the Moon's average (3.3), and also why tektites, just like Earth eruptive rocks, are relatively more rich in uranium and thorium than are meteorites. Thus, lunar volcanism may enter the tektite picture, at least indirectly. At the same time, the recent experiments of Charters and Summers on hypervelocity impact in stone¹⁴ have indicated a ratio of back splash velocity to impact velocity (about 0.3) which leaves no doubt that it is possible

for meteorites coming from the asteroidal belt to eject debris beyond the Moon's gravitational field. Present knowledge is too primitive to warrant complacency as to how lunar material may have arrived on Earth.

In summary, the new results from the discipline of re-entry aerodynamics assign a cosmic origin to tektites, and point firmly at the Moon as somehow being involved in the act of hurling tektites to the Earth.

This research was conducted during 1959–60 while visiting the University of Manchester Department of Astronomy under the aegis of a Rockefeller Public Service Award. Acknowledgement also is gratefully made to Dr. George Baker for providing much of the necessary data on australites, and to Dr. Max Hey for providing on repeated occasions unrestricted access to the British Museum's fine collection of australites.

MEASUREMENTS OF CAESIUM-137 IN HUMAN BEINGS DURING 1958-59

By G. MAYCOCK, SHEILA W. TERRY, J. VENNART and Dr. M. E. WISE

Radiological Protection Service, Belmont, Sutton, Surrey

EVER since the first reports in 1956¹ that caesium-137, a fission product from nuclear bomb explosions, was present in human beings, there has been considerable interest in estimating the contribution which this material makes to man's radiation dose. In view of this we have, since January 1958, attempted to measure the amount of caesium-137 in all persons who have been referred to us for a measurement of their body radioactivity. By far the largest group of these people were women who had worked in the radium-luminizing industry and had ceased working at the end of the Second World War. There is no reason for suspecting therefore that any of them had been in contact with caesium-137 other than that from nuclear bomb fall-out. They came from a wide area around London, the majority living within 50 miles

of the City, although some came from so far afield as Leicester, Swansea and Folkestone. We are now reporting the results of our measurements up to the end of 1959 on 203 of these luminizers, 182 females and 21 males. Besides measuring their radium and caesium contents we have also estimated their body potassium from a measurement of its naturally occurring isotope, potassium-40. In addition, we have estimated the mean dose of radiation received by these people as a result of the caesium-137 in their bodies. For comparison, we are including the results of caesium-137 measurements and calculations of dose for the same period on 16 members of the staff of the Radiological Protection Service.

The amounts of all three materials were estimated by measuring their gamma-ray activities. This was

done in a low-background laboratory using, as the detector, four sodium iodide (thallium activated) crystals situated above the surface of the body. The crystals were optically coupled to photomultiplier tubes, the outputs of which were amplified and fed to a 100-channel pulse-height analyser.

All persons were measured for a period of 1 hr., preceded or followed by a measurement of the background with a water-filled inert model of the human body weighing 70 kgm. in place of the subject. The amounts of the radioactive materials in the people were then determined by comparing the gamma-ray spectrum from each subject with that from calibration sources. It was assumed, in accordance with the views of the International Commission on Radiological Protection², that caesium-137 and potassium would be uniformly distributed throughout the whole body and that radium would be uniformly distributed in the skeleton only. For caesium-137 or potassium, the calibration sources were polythene models of the human body filled with solutions either of caesium-137 chloride or of potassium chloride of known concentration. We have found that the calibration so obtained varied very little with the size of the model. Calibration for radium consisted of determining the response to a point source of radium at several positions along the central axis of the model used for the background measurements. The positions used corresponded to the anatomical regions, head, thorax, pelvis, thighs, legs and arms. In order to obtain a calibration which would approximate to that from a uniform distribution of radium in the skeleton, the contribution from the source at each position was weighted according to the mass of the skeleton in each of the six regions.

Caesium-137 and potassium-40 emit single gamma-rays of 0.66 MeV. and 1.46 MeV. respectively, and the scintillations which they generate in the crystals following photo-electric absorption produce peaks in the counting-rate spectrum obtained from the 100-channel analyser. The body burdens of caesium-137 and potassium-40 were determined from the counting-rate in their respective photo-peaks. However, some photons from potassium-40 lose energy due to scattering in the body and in the apparatus, and then contribute to the counting-rate in the caesium-137 photo-peak. An appropriate allowance must be made for this when estimating caesium-137. An additional uncertainty arises when the subject also contains radium, since this element, together with its radioactive daughters, emits a series of gamma-rays with energies ranging from 0.2 MeV. to 2.4 MeV., and so contributes to the counting-rate in both the caesium-137 and potassium-40 photo-peaks. The radium burden of the subject may be determined unambiguously from the counting-rate corresponding to photons having energies greater than that from potassium-40; in practice, an energy-band from 1.7 MeV. to 2.6 MeV. was used. It is clear, however, that where radium poisoning is suspected, even if the radium burden appears to be zero, an additional uncertainty is introduced into the measurement of caesium-137 and potassium-40 by the error of the radium measurement. For this reason, the standard error of estimating potassium due to counting errors alone increases from 8 gm. where radium can be ignored to 13 gm. for a luminizer, and that of caesium-137 from 1 m μ c. to 2 m μ c. These additional errors vary only slightly with the radium content. As the radium burden increases, however, the identification

of the caesium-137 and potassium-40 photo-peaks becomes increasingly difficult, and it was necessary to limit the cases selected to those having small radium burdens. The 203 luminizers selected all contained less than 0.02 μ c. radium-B in equilibrium with radium-C, the principal gamma-emitting daughters of radium; these were about 85 per cent of the luminizers referred to us.

The principal interest in these measurements is in estimating the radiation dose from caesium-137, and this depends on its concentration in different parts of the body. It has been suggested by Langham and Anderson³ that since caesium is chemically similar to potassium they might also behave the same metabolically. These authors and others⁴ have therefore expressed the concentration of caesium-137 in the body in terms of a caesium-137/potassium ratio. From a mean value of this ratio for a group of individuals, they have calculated the mean radiation dose to the group, assuming that the average man contains about 140 gm. potassium and that the caesium-137 is uniformly distributed throughout his body of weight 70 kgm. However, if the isotope is distributed uniformly throughout all body tissues, it is important to know the way in which caesium-137 varies with the weight of the individual. We have therefore analysed the way in which caesium-137 varies with body-weight and potassium in the largest group of our series of measurements, namely, the 182 female luminizers. Their average age was 41.6 yr. with a standard deviation of 8.5 yr. The youngest member of the group was 27 and the oldest 75.

In order to test any possible trend of the body-burden of caesium-137 with time, the results for eight quarters during the period January 1958–December 1959 were analysed separately. For each quarter it was possible to fit a multiple linear regression of caesium-137 on potassium and body-weight. This fit was compared with the linear regression of caesium-137 on either weight alone (ignoring potassium) or on potassium alone (ignoring weight). It was found that there was a small increase of caesium with both body-weight and body potassium. However, the correlation of caesium-137 with potassium could be entirely accounted for by the fact that both potassium and caesium-137 tend to increase with increasing body-weight. (The increase of potassium with increasing body-weight is well known⁵. In our group of females, the least squares fit to all 182 measured values was $K = 71 + 0.51 W \pm \Delta$, where K is the potassium content in gm., W is the body-weight in kgm., Δ is a random variable with zero mean and standard deviation of 15 gm. The standard error of the estimate of the slope was 0.12. Anderson⁶ also finds a non-proportional increase of potassium with body-weight that is about the same as ours, but for the same body-weight the average potassium values found by him are about 15 gm. less than ours.)

In other words, an equally good fit to the data was obtained by the linear regression of caesium-137 on weight alone. The slope of the line was actually calculated for each quarter and its variation appeared to be random. Since we would not expect it to change with time, a mean value was taken for all eight quarters. The fitted parallel lines for the separate quarters are given by:

$$Z = A + Bx \pm e$$

where Z is the caesium-137 content of any individual in the group in m μ c.; A is the average caesium-137

Table 1. AVERAGE CAESIUM-137 CONTENT OF AN INDIVIDUAL OF WEIGHT 60 KGm.

	No. of people measured	A. (in $\mu\text{mc.}$)
1958	1st quarter	11
	2nd "	22
	3rd "	25
	4th "	36
1959	1st quarter	31
	2nd "	22
	3rd "	10
	4th "	25

content of an individual of weight 60 kgm. and is given in Table 1 for each quarter; B is $0.051 \pm 0.017 \mu\text{mc./kgm.}$; x is (body-weight - 60) in kgm. ϵ is a random variable with zero mean and standard deviation of $2.24 \mu\text{mc.}$ (a large fraction of this may be attributed to the standard deviation of the counting ($2 \mu\text{mc.}$), so that the standard deviation attributable to individual variations about the mean is about $1 \mu\text{mc. caesium-137}$ [$\sqrt{(2.24^2 - 2^2)}$]).

Table 1 shows that there is no obvious trend of A with time. The result for the second quarter of 1959 appears to be low. This result was not due to any change in the sensitivity of the apparatus, nor does it appear that the ages of the persons examined in this period or the localities in which they live present any unusual features. In the absence, therefore, of any explanation for the low value, a mean value of A was calculated for all eight quarters. This was found to be 5.5, so the average caesium-137 content of an individual in the series during 1958 and 1959 is given by:

$$Z = 5.5 + 0.051 x \mu\text{mc.} \quad (2)$$

or

$$Z = 2.44 + 0.051 W \mu\text{mc.} \quad (3)$$

where W is the body-weight in kgm.

Although this represents only a small increase with body-weight, it is much too large to be attributed to chance. Obviously, the caesium-137 content in different people is not proportional to their body-weight, nor to their potassium.

As yet there is no information available to indicate whether caesium-137 is better correlated with any body parameter other than total body-weight, and we have therefore assumed that it is uniformly distributed throughout the body. Following the calculations outlined in the Recommendations of the International Commission on Radiological Protection¹, the average dose-rate to the whole body, D , for an individual of weight W kgm. and caesium-137 content $Z \mu\text{mc.}$ is given by:

$$D = 11 \frac{Z}{W} \text{ m.rems/year} \quad (4)$$

The value of D for a female luminizer during the period in question may then be derived from equation (3):

$$D = \frac{27}{W} + 0.56 \text{ m.rems/year}$$

The lowest weight in the 182 cases was 33 kgm. and the highest 95 kgm. The corresponding dose-rates are about 1.4 m.rems/yr. and 0.8 m.rems/yr. respectively. About half this range of body-weights would include nearly two-thirds of the 182 cases. If the radioisotope is not uniformly distributed throughout the body, some body-organs will, of course, receive a greater dose.

The number of persons measured in the other three groups, the male luminizers and the male and female staff at the Radiological Protection Service, were too small to justify an analysis of the type described above. We have, however, compared their measured caesium-137 content with those which would be predicted by equation (3) and the mean values for each group are given in Table 2. The measured caesium-137 content of the male luminizers during 1958 and 1959, and of the female staff at the Radiological Protection Service during 1958, were not significantly different from those predicted. However, the measured values were higher than the predicted values for the male staff at the Radiological Protection Service during 1958 and for both male and female staff during 1959. The reason for these higher values is not obvious. It is possible for members of the staff at the Radiological Protection Service to have ingested or inhaled these small additional amounts of caesium-137 while at work, but the people found to have most caesium-137 were not those exposed to the greatest risk. (It might be noted that the staff at the Radiological Protection Service are much younger than the luminizers; mean ages 24 against 42 for the females and 25 against 50 for the males).

The radiation dose-rate for each individual was calculated from the measured caesium-137 content using equation (4). The mean values for each group are given in the final column of Table 2. They are very similar to those obtained for the female luminizers, and again there was no obvious change with time. This was in marked contrast to the local gamma-ray dose-rate from fission products on the ground, which changed appreciably during the same period².

Table 2

Subjects	No. measured	Mean caesium-137 content (μμc.)		Mean dose- rate (m.rems/ yr.)
		Measured	Predicted	
		1958		
Male luminizers	6	6.8±1.2	5.8±0.3	1.2±0.2
Male R.P.S. staff	10	9.4±0.8	6.0±0.1	1.5±0.1
Female R.P.S. staff	5	5.6±0.4	5.6±0.2	1.0±0.1
		1959		
Male luminizers	15	5.8±0.8	6.1±0.1	0.8±0.1
Male R.P.S. staff	6	10.0±1.8	6.1±0.3	1.6±0.3
Female R.P.S. staff	4	7.2±0.4	5.8±0.1	1.4±0.1

In 1958 and 1959, therefore, the mean annual dose received by the adults measured, due to caesium-137 in the body from nuclear test explosions, was less than 2 per cent of that from natural sources, which is about 100 m.rems/yr. (ref. 7). It was also small compared with, for example, the difference of about 20 m.rems/yr. between the doses received from the natural background by persons in Leeds³ and Belmont⁴.

THE EPIDERMAL CELL AND THE METAMORPHOSIS OF INSECTS*

By PROF. V. B. WIGGLESWORTH, C.B.E., F.R.S.

THE visible form of the insect is defined by the outer skin or cuticle; which is the product of the single layer of epidermal cells lying beneath it. The form of the insect is thus determined by the growth changes and the secretory activity of the epidermal cell. My purpose is to approach the subject of metamorphosis through a consideration of the physiology of the epidermal cell.

The epidermal cell is interesting because it combines within itself so many functions, actual and potential—social functions as a member of the community of cells of which it forms a part, and individual functions where it is concerned primarily with its own affairs. The cell that is used to illustrate this theme is the ordinary epidermal cell of the abdominal wall in the blood-sucking bug *Rhodnius prolixus*. In its resting state this cell is flattened and attenuated. But if a wound is made in the integument, the dormant epidermal cells are stimulated to activity. The injured cells die, and their autolytic products diffuse out and 'activate' the surrounding cells; their cytoplasm increases and so does its ribonucleic acid content; mitochondria become swollen and more numerous. These activated cells migrate by amoeboid movement to the wound, leaving a peripheral zone of sparse cells among which active mitosis follows and restores the normal cell density.

The response of the epidermal cells to lack of oxygen is quite different. They normally are furnished with oxygen by a rich supply of tracheoles. If the trachea to an area of the epidermis is cut, the epidermal cells restore the supply by sending out elongated filaments which attach themselves to the air-filled tracheoles of a neighbouring area and pull these towards them. These filaments may be 100–150 μ long; they are clearly contractile structures which are re-absorbed into the cell when their task is done. By this means tracheoles may be brought in from distances up to 750 μ .

The chief function of the epidermal cell is the provision for growth; that is, the secretion of a new and larger cuticle and the moulting of the old cuticle. The growth process in *Rhodnius* is initiated by the meal of blood. This distends the abdomen and sends a nervous stimulus to the brain which causes the neurosecretory cells to discharge their hormone. This activates the thoracic gland and causes it in turn to secrete the growth and moulting hormone (ecdysone).

The effects of the moulting hormone resemble those which follow injury. The cells are 'activated' within a few hours. By four days, cell division has begun, and by seven or eight days the epidermis forms a regular columnar epithelium ready to begin the deposition of the new cuticle. This is a complex process involving the secretion and subsequent expansion of the lipoprotein layer (cuticulin), and deposition of the inner layers of chitin and protein. During this most active phase, the epidermal cell has an elaborate cytological structure; it contains granules of a pterin pigment, great amounts of

ribonucleic acid, abundant filamentous mitochondria, innumerable double membranes of endoplasmic reticulum, glycogen and various demonstrable enzymes.

When the new cuticle is nearing completion, the epidermal cells produce and discharge the enzymes protease and chitinase, which digest the inner layers of the old cuticle and absorb the products of digestion through the substance of the new cuticle. Then they secrete a mixture of protein and phenolic substances which impregnate the cuticle and form a film over the surface. They then secrete wax which crystallizes over the surface to form a waterproof film. Finally, when the residue of the old skin is shed, they secrete the phenoloxidase which oxidizes the phenolic substances to the quinones that tan and harden the cuticle, and the tyrosinase which forms the melanin pigment of the blackened regions.

Thus the epidermal cell is a functional cell with an amazing range of chemical and physiological activities. But at the same time it is an embryonic cell which retains a large capacity for differentiation.

During each moulting stage the ordinary epidermal cell may retain its ordinary form or it may differentiate to produce (i) a pair of oenocytes, perhaps responsible for lipoprotein synthesis; (ii) a dermal gland made up of four cells which contributes a layer of 'cement' to protect the waterproofing wax; (iii) a small sense organ or sensillum made up of four cells one of which is a primary sense cell that gives rise to an axon growing inwards and ultimately finding its way to the central nervous system.

It may be that this differentiation among the epidermal cells is controlled by gradients of some chemical inductor substance; and there is evidence for the existence of some kind of 'cytoskeleton' within the epidermal cell which determines its polarity in the general integument.

Apart from this differentiation which can be observed during post-embryonic life, the epidermis has already become differentiated during embryonic development into the pattern which forms the basis of the body-form. When the epidermal cells migrate and multiply during the repair of an injury, they carry with them the potentiality to form their specific component of the body pattern—such as black pigment spots or intersegmental membrane. At the next moult, when the new cuticle is laid down, there is found to be a corresponding displacement of the pattern.

Now the pattern of the abdomen in the adult *Rhodnius* is very different from that of the larval stages; and if injuries of this kind are inflicted in the larva, there are quite different changes produced in the pattern of the adult. These results serve to emphasize that the adult pattern is already latent within the larval cells; and that when these cells divide, the capacity to form particular elements in this adult pattern is transmitted to the daughter cells. But these properties remain latent and un-realized until metamorphosis occurs.

Metamorphosis is controlled by hormones. Throughout the larval stages the corpus allatum, a

* Substance of a Royal Society Tercentenary Lecture delivered on July 28.

small gland immediately behind the brain, secretes the so-called 'juvenile hormone' or 'neotenin'. In the presence of this hormone, the epidermal cells all lay down cuticle of larval type. Their capacity for forming adult cuticle remains latent. But if growth and moulting take place in the absence of the juvenile hormone, the latent adult characters are realized, and adult cuticle is laid down. That is what happens in the last stage of *Rhodnius* when metamorphosis occurs.

As can be proved by implantation of the corpus allatum or by the application of active extracts of the juvenile hormone to the surface of the insect, the hormone acts directly on the epidermal cell, producing localized patches of larval cuticle. Under experimental conditions, the adult *Rhodnius* can be induced to moult again; and if the cells are exposed to the juvenile hormone they will lay down cuticle showing a partial return to larval characters—a partial reversal of metamorphosis.

Thus the epidermal cell has an extensive latent capacity for differentiation. It can differentiate to give rise to one or other of the various elements which make up the spatial pattern of the integument:

hairs, pigment spots, intersegmental membrane and so forth; and the same cell can produce this element in cuticle of larval type or of adult type.

The different elements in the pattern may perhaps be produced by differences in the concentration gradient of one or more chemical substances. That certainly seems to be true of the differentiation between larva and adult. Intermediate forms can be produced by intermediate amounts of juvenile hormone. In insects which have a pupal stage, there is evidence that the larva is produced in the presence of a large amount of juvenile hormone; the pupal form arises when only a very small amount of juvenile hormone is present, and the adult appears in the absence of juvenile hormone.

The larva, pupa and adult are three forms in a polymorphic animal the manifestation of which is controlled by the timing and amount of juvenile hormone secretion. According to this way of looking at things, metamorphosis, polymorphism, and the differentiation of the various parts of the body are closely analogous phenomena, each of which can be described in terms of the controlled realization of genetic potentialities in the epidermal cell.

LEADERSHIP IN RURAL SOCIETIES

ON Friday, September 2, the Geographical and Anthropological Sections of the British Association for the Advancement of Science held a joint symposium at Cardiff on "Leadership in Rural Societies", under the chairmanship of Lord Rennell of Rodd. The organizers of the symposium had arranged for four opening speakers drawn from England, Scotland, Ireland and Wales, respectively, hoping in this way to obtain as complete a coverage as was possible of the general conditions in the British Isles at present. The opening speakers dealing with sample studies drawn from England and Scotland were lecturers in geography, while those who dealt with Irish and Welsh conditions were university teachers specializing in social anthropology.

Two matters were at once apparent. The four opening speakers were concerned with the rapid decline of native leadership in face of the ever-increasing centralization of authority and control in present-day society in Britain. Leadership in rural societies was becoming leadership from without, more particularly at the hands of agricultural advisers. Secondly, the geographers were obviously reading papers in social anthropology and not in geography. Although this was inevitable in view of the topic under discussion, it did, nevertheless, prevent the symposium being in any sense a joint discussion. Professional geographers in the audience felt that in the very nature of the case they had little to contribute.

The opening speaker (or, more accurately, speakers, as Mr. H. A. Molesley read a paper on "Leadership and Innovation in the Crofting Communities of the Outer Hebrides" of which he was the joint author with Mr. J. B. Card) had a considerable advantage. The crofting communities of the Outer Hebrides represent on one hand a remote rural society on the very fringes of centralized control, yet, on the other hand, before the days of agricultural advisers, management under such a system of partly co-operative farming tended to be primitive, no one wishing

to take the onus of introducing changes and few, if any, of the shareholders had sufficient knowledge to know what changes were desirable and what was feasible. So long ago as 1919 an agricultural adviser was appointed for Lewis and resident advisers were appointed for South and North Uist in 1941 and 1954. The advisers are members of the staff of the North of Scotland Agricultural College, and this alone gives them a status which they would not have if they were regarded merely as government officials. Moreover, being permanently resident, they have become accepted as members of the community. The constant presence of such a source of advice is a very real re-assurance to the crofters embarking on some new scheme. In this way the agricultural advisers have taken over the functions of leadership and innovation in agriculture which have long been defunct. It was pointed out that in the Hebrides this natural reluctance to adopt innovations applies not only to agriculture but also to industrial and commercial pursuits. This is particularly the case with the fishing industry. The Harris tweed industry, however, provides the outstanding and perhaps the best-known example of initiative and enterprise; but, nevertheless, mainland interests may yet swallow up the one native industry which has really flourished in the Hebrides. The lack of natural leadership in these islands can, therefore, be attributed to inhibitions due to inherent conservatism, the patriarchal influence and the tradition of equal shares. Until some means can be devised to diversify the size of agricultural units, the emergence of local natural leaders is unlikely.

No other opening speaker had such a remote and isolated society to describe, but Mr. Dafydd Jenkins's study of South Cardiganshire revealed several interesting features. He described the changes in leadership that had taken place within living memory. This Welsh community, like that of the Outer Hebrides, was basically a society organized for the

working of the land. It differed, however, from the Scottish example in that some sixty years ago social stratification was more pronounced than it is to-day. At this time the local gentry were definitely the leaders. It was they who set the standards for emulation and were the innovators of changes in agriculture. This would appear to confirm what Mr. Moisley had said about Hebridean society, namely, that diversification in social structure and in size of land-holding facilitates natural leadership. The contrast between the Anglicized, church-going squires and the Welsh-speaking, Nonconformist peasantry in Wales at the turn of this century was great indeed, and leadership in many matters fell to the squires. Two World Wars and the coming of the Welfare State eclipsed the squires, and Mr. Jenkins showed that those who took their place in South Cardiganshire were not necessarily the agricultural advisers but individuals who for some reason or other did not conform to the conventions of the existing society. For example, a man who was not a member of any chapel and went to the South of France for his holidays might be the first farmer to introduce a tractor or a combined harvester on his farm. Similarly, a farmer who was known to be in debt and had quarrelled with his minister and never appeared in chapel or frequented the local public house was likely to be the first to introduce electrical fencing on his farm. Other farmers later would follow suit. It was clear that in this society there was a sharp distinction between 'bobl y capel' (the chapel people) and 'bobl y byd' (the people of the world). Leadership and innovation after the eclipse of the squires came, as it were, from 'the odd man out' in the local social set-up, and he would inevitably belong to 'the people of this world' rather than to 'bobl y capel'.

The importance of the religious factor in social leadership was stressed also by Miss R. L. Harris, whose contribution to the discussion dealt with leadership in a border community in Northern Ireland. She emphasized the distinction between formal and informal leadership and stressed that the local clergyman was unquestionably the most important formal leader in this society. Members of the community were very reluctant to assume the role of overt leader. Miss Harris paid special attention to the relationships between the local people and such leaders. The local people tended to judge the overt leader on his or her ability to meet outsiders on equal

terms, and it was only natural that Irish people would keep a very close watch on overt leaders from outside the community.

The fourth speaker, Mr. M. Kirk, whose study concerned villages in Yorkshire and Devonshire, made the audience feel the force of the impact of urban civilization on rural life in modern times to a much greater extent than any of the other speakers were able to do. One felt that Mr. Kirk's studies of these English rural communities had the advantage of emphasizing how important are the urbanizing and centralizing forces in modern English life. His title told the whole story—"The Suburban Community in the Countryside". He showed how a large number of English villages were no longer traditionally rural, because so many of their inhabitants included those who had chosen to live in the country, but derived their economic and social status from an urban setting. Village life, in consequence, has decayed. Very often the nominal leader (for example, the elected representative of the community on the rural district council) would be a retired city businessman who had come to live in the village. On the other hand, the native villagers complain that there are not enough men to form a football team, or enough women to run a successful dance. The village is clearly not what it was—in fact, according to Mr. Kirk it has ceased to exist, although its population is actually increasing. Under these conditions local leadership is at a low ebb, while initiative and innovation tend to pass to the central administration functioning through the national ministries.

The general discussion that followed the opening papers may be said to have been disappointing. There are several reasons for this. In the first place, the opening papers were specialized and presented by experts who had the advantage of considerable experience in the field. It is difficult to discuss factual data presented in this way. Furthermore, the four papers were so diverse in character that they did not lend themselves to the formulation of general conclusions, while, in addition, there was the point concerning the geographers already mentioned. One of the speakers in the open forum stressed the importance of university extension classes in rural areas in the training of leaders, while another underlined the fact, already apparent, that as centralized controls increase, local leaders decrease.

E. G. BOWEN

PESTS OF STANDING CROPS

SECTION D (Zoology) of the British Association, during the recent meeting at Cardiff, arranged a morning session under this title since the problems raised in the attempts to understand animal population dynamics are not only interesting in themselves, but also have important applications to studies of crop pests, and some of the basic ideas are relevant to human population studies. At the plenary session of the Association on "World Food and Population", Sir Charles Darwin expressed a point of view close to that of many zoologists, but he spoke for less than five minutes. So it was fortunate that Section D had the opportunity for its own discussion, during the following morning, under the chairmanship of Mr. H. R. Hewer.

Prof. G. C. Varley, of Oxford, sought to relate the contribution of zoologists to problems of human food supply and human population. The symposium of the previous day showed the extent to which men of science are still working as if in watertight compartments. Their work is unco-ordinated, and in human affairs its impact is in opposing directions. Advances in medicine have enormously reduced human suffering and (to our satisfaction as individuals) increased our expectation of life. The reduction of mortality from disease and the increased fertility which accompanies good health have, however, increased the rate of population growth in many parts of the world.

Agricultural experts tend to accept as inevitable

a great rise in human population, and rightly claim that if given the means they can provide the extra food required—for the next forty years at least. Is it not time now to take a long view and to consider how the world population is to be stabilized? Present work is tending to make the eventual solution more difficult. If gerontologists find an easy way to prolong human life far beyond the normal span, the resultant change in the age structure of the population and its rapid increase in size might in fact precipitate a great disaster for the human race.

Many zoologists find ideas like those of Malthus still helpful in studies of animal populations. His prediction late in the eighteenth century that "misery and vice" would result if the population of the British Isles rose much further seemed so convincing that plans for a regular census of the population were made. Now, when the population has risen more than fourfold and the standard of living has also improved, how wrong poor Malthus appears! But was not his error simply his failure to foresee the industrial revolution, with its railways, road transport and steamships to bring food to these islands?

Forty years ago, Pearl fitted sigmoid logistic curves to human populations and extrapolated these to find steady limiting values. We shall not know for another century how right he was, but similar logistic curves describe very well the growth of populations of some insects, such as flour beetles, given a regular energy supply in the form of food. The population limit is reached when the birth-rate equals the death-rate; as crowding increases, the death-rate rises and the birth-rate falls. Whether the differences in human birth-rate between urban and country districts are a similar phenomenon is debatable.

The more complex problems of animal populations of two or more species living together are by no means fully understood. Consideration of the energy-flow in such systems helps in understanding them. Solar energy (about 0.1 per cent of it) is made available as human food by crop plants. Insect pests compete for this energy, and themselves serve as an energy source to their predators and parasites, which may be eaten by other animals. The fraction of available energy lost at each stage of conversion is very high. To support the greatest human population, pests must be kept down in numbers. Sir Alexander Fleck suggested that chemists have provided the method to do this and indeed they can give great help; but it must be emphasized that the problems raised are biological problems of some complexity. Animal populations in the wild and laboratory populations under constant conditions both can show violent fluctuations in numbers, the interpretation of which is still a subject for controversy. Although as yet insufficiently tested, mathematical models are available which can explain population-cycles, and some models can explain in principle why insecticides reduce the average population-levels of some pests but increase the population-levels of certain others.

Mr. D. W. Wright, of the National Vegetable Research Station, Wellesbourne, described his work on the cabbage root fly, the maggots of which feed on the plant's root system. The cabbage then suffers from water- and mineral-deficiency and is stunted or killed. Commonly about a third of the yield is lost, but this can be prevented by the careful application of suitable insecticides to the roots. However,

where insecticides like DDT are used broadcast, or applied with plant fertilizers, very severe pest damage may result. This is because a high proportion of root fly eggs, clustered around the cabbage stem, are normally eaten by predatory ground beetles of the genus *Bembidion*, and low concentrations of insecticide affect these wandering predators far more than the relatively immobile maggots. Field experiments designed either to eliminate the beetles, or to concentrate them within certain areas, have shown conclusively the important role these beetles normally take in limiting the severity of damage by the cabbage root fly.

Dr. G. H. L. Dicker and Mr. R. C. Muir, of East Malling Research Station, considered some fruit pest problems. Toxic chemicals are widely used in commercial orchards and the obstacle to success is usually lack of knowledge of the biology of the pests and their natural enemies, and of the behaviour of the chemicals in the field, rather than a shortage of suitable chemicals. Regular applications of insecticides in early spring have virtually eliminated some pests like the once troublesome apple blossom weevil. Codling moth presents much greater problems. This moth lays its eggs on the young fruits of apple over a period of eight weeks or more. Very soon after hatching, the young caterpillars enter the fruits, where they can no longer be reached by insecticides. Whereas DDT suitably applied can remain sufficiently toxic over the long period of caterpillar hatching and will kill most of the larvae before they enter a fruit, trees so treated commonly suffer severe damage from red spider mite, the predators of which are killed by DDT. The use of a further chemical spray to kill the mites was formerly effective, but the mite has now evolved resistance to a wide variety of chemicals. Special spray schedules designed to interfere as little as possible with predators of the mites are at present under investigation both in Kent and in Nova Scotia, and the results are promising.

The basis of plant resistance to insect attack remains poorly understood, but an apple rootstock resistant to woolly aphis is now available; this project took thirty years from its inception to eventual release on a commercial scale. Even so, success may only be temporary: a raspberry variety supposedly resistant to raspberry aphid was found susceptible to attack by a previously untested strain of the aphid.

A paper by Dr. R. F. Morris and Dr. C. A. Miller, of the Forest Biology Laboratory, Fredericton, N.B., Canada, on the population dynamics of some native and introduced forest insects in the Atlantic Provinces of Canada summarized long-term population changes and went a considerable way to suggest causes for them. Many of the native pests of the extensive spruce and balsam fir forests seem to have small population peaks every five to eight years, but never become common enough to cause visible damage to the trees. In contrast, the black-headed budworm has maxima on the average every seven years, and in the late 'twenties and again in the late 'forties trees were defoliated; but the population-level diminished again without the trees being killed. A study of the changes in the numbers of the hymenopterous parasites of the budworm suggests that this is an example of Nicholsonian host-parasite population oscillations. The cycles in widely separated populations in eastern Canada seem to be in phase, which suggests that some common extrinsic factor such as weather has an

effect on the periodicity. Cycles of abundance of the fall webworm can be traced from historical records so far back as 1770. The interval between outbreaks is between nine and thirteen years. In Nova Scotia the population peaks are high enough to defoliate trees whereas in New Brunswick the maxima are never so high; this curious difference in status could provide a lead to new methods of control and it is being investigated.

The spruce budworm is the major native pest of the spruce and balsam fir forests. At intervals of some forty years it has killed the trees over hundreds of square miles. The numerous species of parasites and predators which attack the spruce budworm when its numbers are low seem unable to increase quickly when the budworm outbreaks begin, and indeed seem to shun defoliated areas of the forest. The most recent outbreak began in the middle 'forties and, at its height, to save the trees more than 200 aircraft were used to spray insecticide over some 5 million acres of forest.

The introduced European spruce sawfly caused serious damage to the trees in the 'twenties. Various parasites were then imported and liberated, and some became established. For the past twenty years, these and a virus disease which was apparently introduced accidentally have kept the species below a level at which damage is significant. Time will show whether current projects for the biological control of the introduced winter moth, larch case bearer and balsam woolly aphid will eventually be successful. Only a very few years ago, biological control was regarded as possible only on oceanic islands or perhaps as an exception in California!

These papers are representative of the sort of long-term work which is now being undertaken in agricultural and forest entomology. There is clearly a great need for more applied research, but this will be easier to plan when there is more basic knowledge of the behaviour of pests and their predators and parasites, especially in relation to changes in their food supplies and population densities. G. C. VARLEY

GULIELMA LISTER CENTENARY

MISS GULIELMA LISTER, born on October 28, 1860, at 871 High Road, Leytonstone, Essex, where she died on May 18, 1949 (ref. 1), was one of those distinguished amateur naturalists of professional competence who have done so much to advance and deepen biological knowledge. She came of an intellectual Quaker stock—her father, Arthur Lister, F.R.S. (1830–1908), was a son of J. J. Lister, F.R.S. (1786–1869), and a brother of Lord Lister (1827–1912), the surgeon—and apart from a year at Bedford College she was educated at home. The course of her long life showed her to be able and industrious, economical and generous, a painstaking and accurate observer, and artistic, while her attractive personality gained her many friends. Her interests in natural history were exceptionally wide, and her detailed field knowledge of both the fauna and the flora must frequently have embarrassed specialists. Miss Lister was for many years an active member of the Essex Field Club, towards which she maintained a special affection, the Nature Study Union, and the Linnean Society, and she was twice president of the British Mycological Society. She had many calls on her artistic ability, and made notable minor contributions to botanical art in such works as her cousin F. J. Hanbury's "Illustrated Monograph of the British Hieracia" (1889–98), with its beautiful hand-coloured plates, and in addition did more utilitarian illustrations for Dallimore and Jackson's "Handbook of the Coniferae" (1923), and other publications.

Miss Lister and her father will for long be best remembered as world authorities on the Myxomycetes or Mycetozoa, an interesting, distinctive, and compact group of organisms which, as its names imply, has been approached by botanists and zoologists with a certain ambivalence. The slime moulds, now generally accepted as a fungal group, are aesthetically attractive and are of world-wide distribution. Their classification is based mainly on their macroscopic and gross microscopic characters, and as they make excellent herbarium specimens they have been widely collected and preserved so that ample material is available for their study. It is to the Listers that

much credit must be given for the reasonable chance of success that now attends the attempted identification of a myxomycete from any part of the world.

Arthur Lister, like his father, a wine merchant, had life-long interests in natural history and first turned his attention to Myxomycetes in 1887, his fifty-seventh year. After a hesitant start, he applied himself to the group with vigour, and accompanied by his daughter (as amanuensis and artist, though no mean draughtsman himself) he worked over the collections of Myxomycetes at the British Museum, the Royal Botanic Gardens, Kew, and the Paris Natural History Museum, as well as de Bary's collections at the University of Strasbourg, and as a result the first edition of his "Monograph of the Mycetozoa" appeared in 1894 under the imprint of the British Museum (Natural History). After the death of her father, Miss Lister continued to study Myxomycetes for another forty years. She was responsible for the second edition of the "Monograph" (1911) and for the enlarged third edition (1925) (now unfortunately out of print and much sought after), which were lavishly illustrated in colour due to Miss Lister's generosity.

The "Monograph" is firmly based on specimens, many of which are in the British Museum (Natural History), and its background is well documented not only by the published papers of the Listers themselves and their correspondents but also in a series of seventy-four manuscript note-books (now in the possession of the British Mycological Society*) extending over a continuous period of sixty years, which give a fascinating picture of the day-to-day progress of the investigation, the routine of which went on uninterrupted whether at home in Leytonstone or at the Listers' seaside house at Lyme Regis. The method of notekeeping was simple. Strongly bound, thick, school exercise books of lined paper were used, and notes were entered chronologically. Entries were made giving details of collections examined, the gist of letters received and of the replies, the notes frequently being accompanied by elaborate and often highly artistic water-colour drawings—

executed directly on the lined paper, drawing paper being reserved for illustrations intended for publication. Reprints, original letters, photographs of correspondents and other matter were also loosely inserted. Separate books were devoted to material from special collections such as the Paris Museum or from important correspondents such as T. Petch (when in Ceylon). Each book when completed was indexed, and a general index to the whole series and a letter register were maintained in a folio ledger. Thus they kept their many records under continual review and easily accessible.

It was this interest in Myxomycetes which led to the long association of the Listers with the British Museum (Natural History), which Miss Lister first visited with her father around 1890 when, as mentioned above, she was helping him prepare his "Monograph". She continued her connexion with the Museum until 1939, being virtually honorary curator in charge of the Mycetozoon collection, which she helped to make the most complete and valuable in the world. With the outbreak of war, at the age of seventy-nine, the exigencies of travel made the journey from Leytonstone to South Kensington no longer possible for her.

Those of us old enough to have worked in the Botany Department of the Museum before the Second World War remember both her and her very dear friend, Miss Annie Lorraine Smith, the great lichenologist, for their ready interest, kindness and patience in helping and teaching younger workers.

Many of the Listers' specimens were deposited in the British Museum (Natural History) during their lifetime. Miss Lister bequeathed her mycological library and her Myxomycete notebooks to the British Mycological Society and her personal collection of slides and specimens to Mr. H. J. Howard of Norwich, another amateur myxomycetologist. On his death in 1957 this material was divided between the British Museum (Natural History) and the Royal Botanic Gardens, Kew.

The Linnean Society of London and the British Mycological Society arranged a meeting, held on October 28 at the British Museum, to commemorate the centenary of Miss Lister's birth and her long association with the two Societies and the Museum.

OBITUARIES

Sir George Stapledon, C.B.E., F.R.S.

SIR GEORGE STAPLEDON, who died on September 16, was world renowned as the first director of the Welsh Plant Breeding Station at Aberystwyth; he was indeed its inspiration and the architect of its work during its formative years from 1919 up to the late 1930's.

Reginald George Stapledon was a kindly man and one whose prime interest was the human both as an individual and as part of a community. He was born in 1882, was educated at the United Services College, Westward Ho!, in North Devon, and Emmanuel College, Cambridge, where he read biology under Prof. A. C. Seward. For a period after leaving Cambridge he joined the family shipping concern, but soon returned to Cambridge, where he gained the University diploma in agriculture. In 1910 he became professor of agricultural botany at the Royal Agricultural College, Cirencester, and in 1912 went to Aberystwyth as agricultural botanist. After the outbreak of the First World War he joined the Ministry of Agriculture's Food Production Department in London. At the end of hostilities he became the first director of the newly formed Official Seed Testing Station, Cambridge, but in the summer of 1919 accepted the invitation to establish and to direct the Welsh Plant Breeding Station which was to be set up in Aberystwyth as a result of the monies given for the purpose to the University College of Wales by Sir Laurence Philipps, Bart. (now Lord Milford). Stapledon remained at Aberystwyth until the outbreak of the Second World War, when the Minister of Agriculture invited him to establish the Grassland Improvement Station at Stratford-on-Avon and to become its director. On his retirement in 1945 he joined Dunns Farm Seeds, Ltd., as scientific adviser and was soon invited to join the board of directors, a post he held until his death.

It was as director of the Welsh Plant Breeding Station that Stapledon would wish to be remembered. To him this very rightly represented the central core of his professional work. His influence, however, went far beyond Wales—indeed, it is world-wide. His was a genial personality; he was a man who worked hard and never spared himself if there was a job to do. He had the capacity also to instil into others those same personal qualities for hard work done willingly, loyally and with affection towards the leader. Stapledon was a man of ideas and of great ideals. He will be renowned in history as one of the great, and among grasslanders, as the greatest of them all. He was a notable figure in any gathering, particularly where the conversation and discussion found his interest and were to his liking.

His personal work at Aberystwyth (he himself was the cocksfoot breeder) resulted in the creation of new varieties of herbage plants, and in all essentials the types then selected are still embodied in the 'S.' varieties which are to-day widely used in Britain and in many countries overseas. It was Stapledon's creative mind which outlined the need for the study of pasture plants and to apply existing genetical and agronomic knowledge to this end. He went further, however, and insisted that there should be built up a mass of new knowledge, much of which by now has become embodied in the new science of grassland.

Stapledon was at heart a farmer. His sympathies were with the farmer and with the land. He was at once scientist, artist and humanist, a combination which was bound to culminate in an enthusiasm for applying his science—and indeed all his other talents—and bringing them to bear upon the day-to-day problems of the grassland farmer.

Early in his professional career he recognized that in grass we have a crop, the potential contribution of which to material welfare was not appreciated by the agricultural community itself, let alone by the

nation at large. This concept fired his enthusiasm, with the result that he led the British nation to plough up their derelict pastures and replace them with high-yielding leys. This process still goes on throughout Britain, which at the present time is universally acknowledged as the leader of ley farming techniques among the countries of the world.

WILLIAM DAVIES

Dr. D. Chatterjee

DR. DEBABRATA CHATTERJEE, superintendent of the Indian Botanic Garden, Sibpur, Calcutta, was shot dead at point-blank range on September 24 by one of his subordinates, who, having committed this utterly wanton and senseless crime, turned the gun on himself and successfully brought his own life to an end. It appears that the assassin aspired to a post in the Botanical Survey of India, and although he did not possess the necessary qualifications he fancied that Dr. Chatterjee was not active enough in furthering his claims. Homicidal mania, inflamed by an insane sense of injustice and frustration, was responsible for the death of one of India's leading botanists at the early age of fifty.

Dr. Chatterjee received his early botanical training at the Presidency College, Calcutta, obtaining his M.Sc. in botany in 1937. From Calcutta he proceeded to the University of Edinburgh, where he worked for two years under the late Sir William Wright Smith. He obtained the Ph.D. degree for a thesis

dealing with endemism of Indian plants. On his return to India he worked for a time in the herbarium at Sibpur and then went to Burma as a lecturer in botany at Mandalay College. He escaped to India when the Japanese invaded Burma in 1942 and lectured at the Cotton College, Gauhati, Assam, for four years. He became botanist for India at the Royal Botanic Gardens, Kew, in 1946, and in 1949 was appointed to the post of systematic botanist at the Indian Agricultural Research Institute, which he held for six years. He succeeded Dr. K. Biswas in 1955 as superintendent of the Indian Botanic Garden.

Dr. Chatterjee's botanical interest lay mainly in the taxonomy of Indian and Burmese plants, and he published papers in a number of journals including the *Kew Bulletin*, *Hooker's Icones*, *Nature* and several others. Since leaving Kew he had never really had the opportunity of developing his undoubted taxonomic ability. For part of the time he had to work without an adequate herbarium or library, while during the past few years he had been overwhelmed with the numerous details inherent in the administration of the Botanic Garden. Even so, his loss will be severely felt in India, where there is a conspicuous shortage of competent taxonomists.

At Kew he will be remembered as a congenial colleague who did valuable work for India during the period he worked there.

He is survived by his aged parents and by his only daughter, to whom our sympathy is due. His wife died some years ago.

N. L. BOR

NEWS and VIEWS

Nobel Prize for Medicine

THE Nobel Prize for Medicine, amounting to about £15,000, has been awarded jointly to Sir Macfarlane Burnet, director of the Walter and Eliza Hall Institute for Medical Research and professor of experimental medicine in the University of Melbourne, and Prof. P. B. Medawar, Jodrell professor of zoology and comparative anatomy in University College, London. Both recipients are well known for their work on acquired immunological tolerance, which has initiated a new era in experimental biology and medicine. (See p. 376 of this issue.)

A.R.C. Institute of Animal Physiology, Babraham : Dr. R. Keynes, F.R.S.

A NUMBER of new appointments to senior posts at the Agricultural Research Council's Institute of Animal Physiology at Babraham, near Cambridge, has recently been made.

Dr. Richard Keynes has been appointed head of the Physiology Department. He succeeds Dr. I. de Burgh Daly who was head of this Department as well as being director of the Institute. Dr. Keynes's scientific work has mostly been done in Cambridge, but, during the War, he worked for five years with the Navy on asdic and radar. His best-known researches are concerned with the movement of ions in nerve and muscle and the origin of the discharge in electric fish. He measured the quantities of radioactive sodium and potassium which cross the surface membrane of a single nerve fibre during the passage of

an impulse. More recently he has studied the movements of these ions against concentration differences during recovery, and has become interested in the metabolism of potassium in the whole animal. He has been a member of the editorial board of the *Journal of Physiology* since 1964 and is now chairman. Dr. Catherine Hebb has become head of a Sub-Department of Chemical Physiology.

Dr. T. Gillman

DR. THEODORE GILLMAN succeeds Sir Alan Drury as head of the Experimental Pathology Department. Sir Alan went to Babraham in 1952 and established this Department as an active centre for work on cell surfaces, immunity, and blood groups in cattle and sheep, with especial reference to genetics. Dr. Gillman graduated in the University of the Witwatersrand and became lecturer in clinical pathology. He was appointed professor of physiology in Durban in 1951, but he has not been confined by the title of his department, and has worked, not only on gastric physiology, but also on iron metabolism, malnutrition, neoplasms, and liver disease. Recently he has been interested in tissue reactions in wound healing, the ageing of arteries and the transplantation of tissues. Dr. Gillman is an energetic person; while he was in Durban he built up a large and active department from nothing, replanning the architecture and organizing courses in physiology, biochemistry and pharmacology, and wrote many scientific papers.

Dr. G. D. Greville

DR. G. D. GREVILLE has become head of the Biochemistry Department in succession to Sir Rudolph Peters, who went to Babraham in 1954 and built up a distinguished staff of biochemists. Dr. Greville graduated in Cambridge and then worked during 1932-37 at the Middlesex Hospital in London. He was biochemist to Runwell Hospital for seven years, and returned to the Biochemical Department in Cambridge in 1944. He has worked in many fields, including glucose tolerance, carbohydrate chemistry, blood coagulation and mental disorder, but his main interest has been in tissue metabolism. He was responsible for an early demonstration of the uncoupling effect of nitrophenols and has studied the effects of various metabolic ions. Recently he has published an interesting series of papers on the metabolic changes associated with the swelling of mitochondria.

Dr. Marthe Vogt, F.R.S.

DR. MARTHE VOGT has become head of a new Pharmacology Unit at Babraham. Her early work was done in Berlin under her famous father, Dr. Oskar Vogt, and Profs. Neuberg and Trendelenberg. She came to Britain in 1935 and showed, with Dale and Feldberg, that acetylcholine is liberated at motor nerve endings in voluntary muscle. She worked with Verney in Cambridge during 1935-39 on renal hypertension in dogs. From there she went to the laboratories of the Pharmaceutical Society in London and started work on the adrenal cortex. She showed that the output of hormones in the blood was large compared with the amounts stored in the gland and that adrenaline increased the rate of liberation. She still works on the adrenal cortex and is one of the leading authorities on the subject, but she has also done distinguished work in other fields. In 1946, she followed Gaddum to Edinburgh and became interested in adrenaline and noradrenaline. It was her work, published in 1954, which convinced the world that these catecholamines are likely to play some part in the physiology of the brain, since they have a specific distribution and are affected by such factors as the injection of drugs. This has led to a great deal of work on the biochemical mechanisms by which drugs may cause tranquillity or arousal.

The National Institute of Sciences of India :

Honorary Fellows

THE following have been elected Honorary Fellows of the National Institute of Sciences of India: Prof. D. Bovet (director of therapeutic chemistry, Istituto Superiore de Sanità); Sir John Cockcroft (Master of Churchill College, Cambridge); Dr. W. Shockley (Shockley Transistor Corporation, Mount View, California); Prof. E. C. Titchmarsh (Savilian professor of geometry, Oxford).

The NATO Summer Schools Programme

THE North Atlantic Treaty Organization was created as a defensive organization, and is usually thought of only in a military context. The changing nature of the challenge to NATO countries during recent years, however, has caused NATO to widen its outlook, and in 1957 a Science Committee was established to promote scientific co-operation between NATO countries, and among the schemes adopted is the NATO Advanced Study Institutes Programme.

NATO spent 100,000 dollars in 1959 and 200,000 dollars in 1960 on these 'summer schools'. Grants to individual schools varied between 3,000 and 45,000 dollars, normally being between 10,000 and 15,000 dollars. The grants are used to cover overhead expenses, to facilitate publication of the proceedings, and a considerable part is usually available to subsidize foreign visitors. In 1959 all five schools were on subjects in physics, and in 1960 nine of the fifteen schools were also in physics. Among the other schools in 1960 was a course at the Royal College of Science and Technology, Glasgow, on food science, and another at the Max-Planck-Institut für Tierzucht und Tierernährung at Mariensee dealt with methods of improving productivity with livestock. Both these topics range widely over a number of academic disciplines, and the lecture courses were arranged to survey the whole field. Rather different in intention were the courses on crystallography at the Manchester College of Science and Technology, and on protein analysis at the Medizinische Forschungsanstalt der Max-Planck-Gesellschaft at Göttingen, both of which were highly practical in outlook. Attendance at the schools was not restricted to people from NATO countries.

Naturally, the NATO grant does not cover all costs, but it often enables the quality of the summer schools to be considerably improved by inviting foreign scientists. It is expected that 300,000 dollars will be available in 1961 for the Advanced Study Institute Programme. Courses already arranged for 1961 include the following: theoretical physics (Dr. L. W. H. Trainor) at Montreal; theoretical chemistry (Prof. C. A. Coulson) at Oxford; use of computers in engineering problems (National Laboratory of Civil Engineering, Lisbon) at Lisbon; solid state theory (Prof. W. Dekeyser) at Ghent; medical documentation (Dr. O. Nacke) at Bielefeld. Anyone interested in organizing such a course, and requiring financial assistance from NATO, should write to the Office of the Science Adviser, NATO, Place du Maréchal de Lattre de Tassigny, Paris 16e, before December 15.

Safety in Mines Research

THE annual report of the Safety in Mines Research Establishment of the Ministry of Power for 1959 contains sections devoted to explosives and blasting devices, explosion hazard, rescue apparatus, fire hazard, engineering and metallurgical research, investigation of mining incidents and examination of equipment after mine service, dust measurement and the pneumoconiosis hazard, and testing services (Pp. 66+4 plates. 4s. 6d. net. London: H.M. Stationery Office). Among the most interesting topics of the report are those concerned with firedamp roof-layers, investigation of incidents and pneumoconiosis. During the past two years problems connected with the formation and movement of firedamp roof-layers have been intensively studied and a parameter, the layering number, has been developed which will be of importance in the work of ventilating engineers. A new section, the Incidents Section, has been established within the organization to co-ordinate the work concerned with investigation of actual incidents and to provide men specially trained in scientific aspects of mine disasters, particularly actual underground explosions and fires. Although the pneumoconiosis research has followed broad lines similar to those of previous years, much interest has

been directed towards the development of a gravimetric sampler for measurement of respirable dust, and the opinion is expressed that measuring the mass concentration of respirable dust may prove more useful and convenient than the present practice of measuring particle-number concentrations. Altogether a variety of topics is covered within the sections of the report and many of these are of scientific and technological interest to a wide range of industries in addition to the mining industry.

The International Journal of Heat and Mass Transfer

THE wide application of heat and mass transfer, including almost every form of engineering, chemistry and physics, has made it inevitable that much valuable information has hitherto appeared in specialized journals which pass unnoticed by workers in other fields, who might well find use for such data. The very large number of papers now published indeed makes it impossible to examine all the journals containing such subject-matter. The addition of a new monthly journal, published by the Pergamon Press, and entitled *The International Journal of Heat and Mass Transfer*, will be welcomed by all engaged in such work (1, No. 1; June 1960. Pp. 114. Subscription rates: (A) for Libraries, Government Establishments, Research Laboratories, etc., £7 (20 dollars) per vol.; (B) for individuals who place their orders directly with the publisher and certify that the journal is for their personal use, £5 5s. (15 dollars) per annum). Six distinguished editors drawn from Great Britain, the United States, U.S.S.R. and Germany, assisted by some fifty advisers representing major academic and industrial concerns from all over the world, should ensure a truly international journal with a succession of papers of high standard. The first issue contains an editorial article and ten papers, two of which are in German, one in French, the remainder in English; all papers have an abstract in English, French, German and Russian. There is also a "Bibliography of Heat Transfer", presumably of publications written in the past few years only, though this is not stated. Research workers already familiar with advanced concepts will find the contents of the most value. It is to be hoped that the editors will from time to time include fundamental but more elementary articles for the benefit of less erudite students, such as those in their first year of Ph.D. work.

Bibliography of Research at Oak Ridge National Laboratory

A LIST of articles by members of the staff of the Oak Ridge National Laboratory (operated by the Union Carbide Corporation for the United States Atomic Energy Commission) published during 1959 in technical journals has been issued by the Laboratory, and requests for reprints where available, as indicated by the prefix *R*, should be addressed to the Central Research Library at the Laboratory (Pp. v + 84. Oak Ridge, Tennessee: Oak Ridge National Laboratory, U.S. Atomic Energy Commission, 1960). The articles are arranged alphabetically by author under nine divisions: biology; chemistry; general; health physics; instrumentation; mathematics; metallurgy and materials; physics; and technology. There is an accompanying list of reports issued by the Laboratory, and these, except when indicated as "Not for sale", should be ordered through

the Office of Technical Services, Department of Commerce, Washington 25, D.C. A third list, similarly arranged, records the titles of papers presented at scientific meetings, and requests for information regarding these papers should be addressed to the authors concerned. Titles of eighteen theses completed at the Laboratory during the year are given in a fourth list, alphabetical by author, and finally there is a list of sixty-eight inventions disclosed during the year.

Research Into Electricity Supply

As a postscript to an article on the supply of electricity in Great Britain, Arthur Palmer suggests unified areas where research could be carried out (*Research Applied in Industry*, 13, No. 9: September 1960). These include investigations into fundamental questions of electricity production and use: for example, ways and means of escaping the limitations of the thermodynamic cycle and methods of solving the outstanding energy storage problem; investigations into reductions of cost in all the fields of generation, transmission, distribution and utilization—this is primarily a scientific and engineering matter, but it must occasionally take account of psychology or even sociology; investigations into techniques for reducing the social nuisance of electrical processes—in an island packed with more and more human beings demanding simultaneously the often mutually contradictory ends of higher and better standards, this is no easy task; and investigations into the possibility of maintaining human interest in an industrial environment which when ideally organized and arranged will record the almost effortless glide of electrons from genesis to consumption.

Poison Sprays and Wild Life

A JOINT Committee of the Royal Society for the Protection of Birds and the British Trust for Ornithology has been formed under the chairmanship of Mr. S. Cramp to study the effect of toxic chemicals on birds. The Committee is anxious to obtain evidence of kills of birds due to agricultural chemicals used in sprays or in the form of seed dressings. The basic information needed is the date and locality of the kills, the species and number of birds affected and the chemical used. The Committee would appreciate prompt notification of birds the death of which is thought to be due to agricultural chemicals, so that if necessary corpses may be collected for chemical analysis. Information should be sent to the secretary of the Committee, Mr. P. J. Conder, Royal Society for the Protection of Birds, 25 Eccleston Square, London, S.W.1.

Insulin

A RECENT issue of the *British Medical Bulletin* deals with insulin in its varied aspects (16, No. 3; September 1960). Prof. Charles H. Best describes his pioneer work with Banting and developments which have occurred during the past forty years. This is followed by an account by Dr. F. Sanger of the chemistry of insulin based on his Nobel Prize Lecture. Other articles include one by Dr. Ieun Harris on the chemistry of pituitary polypeptide hormones; methods of insulin assay by G. A. Stewart; insulin antibodies by Dr. P. H. Wright; the action of insulin on carbohydrate metabolism by Dr. R. B.

Fisher; fatty acid metabolism by Drs. S. J. Folley and A. L. Greenbaum and the mechanism of the action of insulin by Dr. P. J. Randle and Prof. F. G. Young. Prof. F. G. Young has acted as scientific editor of this issue.

Inhibition of Development in Rust Fungi

D. J. SAMBORSKI and F. R. Forsyth have reported on the inhibition of the development of rust fungi, on detached wheat leaves, by various metabolites, antimetabolites and enzyme poisons (*Canad. J. Bot.*, 38, 487; 1960). This is part of a series of investigations in which attempts are being made to correlate changes in the reaction of the pathogen with changes in endogenous levels of substrate in the host. In the experiments, detached leaves of Little Club wheat were floated on solutions containing benzimidazole and the compound being tested. The effects of purine and pyrimidines, vitamins, amino-acids, carbohydrates and enzyme poisons were examined. A number of these compounds inhibited leaf and stem rusts at concentrations that were not injurious to the host. Of the purines and pyrimidines tested, thymine and the analogue azathymine were the only effective inhibitors. The antivitamin oxythiamine was inhibitory, the inhibition being completely reversed by thiamine. A few natural amino-acids, notably histidine, isoleucine, methionine and serine, inhibited rust development. The inhibition was reversed by glycine in all cases except with serine. Amino-acid analogues, particularly canavanine, ethionine and *p*-fluorophenylalanine, were very good inhibitors, the inhibitions being reversed by comparable levels of arginine, methionine and phenylalanine, respectively. The carbohydrates lyxose, xylose, sorbose, and all the sugar alcohols tested were effective inhibitors of rust development. Of the enzyme poisons tested, sodium fluoride and sodium azide differentially inhibited rust growth.

The Gairdner Foundation: Awards

AWARDS totalling 30,000 dollars for medical work in arthritis and heart disease have been made by the Gairdner Foundation to four American and two British medical scientists as follows: Prof. John H. Gibbon, jun., professor of surgery and director of surgical research, Jefferson Medical College, Philadelphia; Prof. William F. Hamilton, professor of physiology, University of Georgia School of Medicine; Dr. Karl Meyer, dean of medicine at Columbia University, New York; Prof. Arnold R. Rich, Baxley professor emeritus of pathology, Johns Hopkins University; Prof. J. McMichael, professor of medicine, University of London; Prof. J. H. Burn, recently professor of pharmacology, University of Oxford. The awards will be worth 5,000 dollars each, and are prizes for achievements rather than for the support of future research.

U.S. Society for the Study of Development and Growth

THE following were elected officers of the U.S. Society for the Study of Development and Growth for the year November 1960–November 1961: *president*, Prof. William P. Jacobs (Princeton University); *secretary*, Prof. Armin Braun (Rockefeller Institute); *treasurer*, Prof. H. Clark Dalton (New York University). The other members of the

executive committee are: Prof. Clifford Grobstein (newly elected), and Profs. Arthur Galston and Dietrich Bodenstein.

The Association of Clinical Biochemists

THE Association of Clinical Biochemists has elected the following officers for the session 1960–61: *president*, Dr. C. P. Stewart; *chairman*, Dr. A. L. Latner; *honorary treasurer*, Dr. R. Gaddie; *honorary editor*, Mr. H. Varley; *honorary secretary*, Dr. J. H. Wilkinson (Westminster Medical School, Horseferry Road, London, S.W.1).

Announcements

MR. A. D. MCKNIGHT, executive commissioner of the Australian Atomic Energy Commission, has been elected chairman of the Board of Governors of the International Atomic Energy Agency for the next year.

THE eleventh session of the United Nations Educational, Scientific and Cultural Organization is to be held at Unesco House, Place de Fontenoy, Paris, during November 14–December 13. The main subject for discussion will be International Co-operation for Oceanographic Research.

AN all-day session of the Welsh Soils Discussion Group will be held in the Department of Geography and Anthropology, University College, Aberystwyth, on November 16. The theme will be: "Glaciation in Wales as related to Soil Profile Development". Further information can be obtained from Mr. James A. Taylor, Department of Geography, University College of Wales, Alexandra Road, Aberystwyth.

A SYMPOSIUM on "Inorganic Polymers" is being sponsored by the Chemical Society, and will be held at the University of Nottingham during July 18–21, 1961. Further information can be obtained from the General Secretary, Chemical Society, Burlington House, London, W.1.

THE 1960 meeting of the American Association for the Advancement of Science will be held in New York City during December 26–31. Further information can be obtained from the director of public information for the meeting, Sidney S. Negus, Medical College of Virginia, Richmond, Virginia.

THE Plant Phenolics Group is holding a one-day meeting on "The Stereochemistry of Natural Phenolic Compounds" at the Department of Engineering, University of Bristol, on December 16. Further details can be obtained from the Honorary Secretary of the Group, Low Temperature Research Station, Downing Street, Cambridge.

THE third international conference on "Analogue Computation" will take place in Belgrade during September 4–9, 1961. The conference is being organized by the International Association for Analog Computation. Further information can be obtained from L. Radanović, Yugoslav Committee for Electronics, Telecommunications, Automation and Nuclear Engineering, Tarazije 23/VII, Belgrade.

DIAMOND PHYSICS

A CONFERENCE on diamond physics was held during September 22-23 at the J. J. Thomson Physical Laboratory, University of Reading, under the auspices of the Institute of Physics and the Physical Society. More than a hundred delegates attended, and twenty-one papers were presented, most of which originated in Great Britain, but contributions were also received from the United States and one from Stockholm. Most of the contributions were experimental; two theoretical papers on related topics were those of P. Ewald (United States) on the electron density of diamond and of H. Bolton and H. Clark (Newcastle) on the nature of the bond orbitals. It was generally agreed that the electron density is much less concentrated than the word bond might imply, but it still remains very difficult to account theoretically for the intensity of the (222) X-ray reflexion observed in some specimens.

Two papers were devoted to synthetic diamonds. That on their production by E. Lundblad (A.S.E.A., Stockholm) compared different methods of synthesis using various catalysts and conditions of temperature and pressure but no direct transition of graphite to diamond has yet been achieved. The results therefore confirm those of the General Electric Co. (United States).

G. Kennedy (United States) and others, however, pointed out that they were convinced that the pressures at present quoted on the Bridgman scale were about 30 per cent above the true value at pressures greater than 25,000 atm. Consequently diamond formation occurred considerably below the region indicated by the Simon graphite-diamond equilibrium curve, which therefore needed revision.

The diamonds produced synthetically may have either type I or type II characteristics according to the method of production.

The other paper, by S. Tolansky (University of London), on optical and interferometric studies on the surface characteristics of diamonds compared the synthetic products from several different sources. A wide variation in crystal perfection was observed, some batches of specimens consisting of 'hopper-type' crystals whereas other batches were relatively perfect. Growth spirals were detected on specimens from one batch.

There were several contributions on semi-conducting diamonds. H. Farnsworth and J. Marsh (United States), using normal incidence on the (100) face, showed that the electron diffraction pattern below 350 eV. contained no half-integral order surface grating beams, thus indicating that the positions of the atoms in the surface monolayer are not displaced from their 'normal' positions as for silicon and germanium. Changes in the intensity of the diffraction pattern on heating treatment are interpreted in terms of variations in adsorbed oxygen, but there was some disagreement on details of the interpretation.

F. C. Champion and J. Male (London) compared the luminescence excitation spectrum of a semi-conducting specimen with its absorption spectrum and showed that the former method sometimes gave information absent from absorption data. For example, it showed quite clearly a level agreeing

with an acceptor-level at 0.35 eV. from the valence band. Measurements of the anisotropy of the magnetoresistance in three oriented crystals of *p*-type semi-conducting diamond by P. J. Kemmey and E. W. J. Mitchell (Reading) were compared with calculations based on the approximate model of two warped and one spherical energy band surface, degenerate at $K = 0$.

Contributions to the study of graphitization were made by M. Seal (United States) and by T. Evans and C. Phaal, and Evans and H. Sauter (Reading), the two latter emphasizing the aspect of etch-rate determination and etch-pit orientation on diamond surfaces. It was shown that trigons oriented such that the apices of the triangles on the octahedral face were pointed towards the sides of the face, as in naturally occurring trigons, could be produced by etching with an oxygen and water vapour mixture above about 800° C. Below that temperature the trigons had the usual etch orientation with sides of the trigons parallel to the sides of the crystal face. High-temperature and high-vacuum graphitization experiments on diamond were also described by V. Howes (Reading).

Experiments on irradiation damage to diamonds by electrons of energies up to 2 MeV. were described. Changes in the optical absorption of a type IIa diamond near 2 eV. were compared with the theoretically expected rate of defect production and agreement below 1 MeV., obtained if the displacement energy is $E_d = 80$ eV. Corresponding measurements on the change of resistivity of a IIb diamond with radiation dosage were in agreement with the absorption data up to 1 MeV., but above this energy C. Clark, P. J. Kemmey and E. W. J. Mitchell (Reading) found poor agreement, the explanation of which is uncertain. D. Palmer and C. D. Clark (Reading) showed from corresponding absorption changes with temperature that complex annealing processes occurred indicating a wide range of activation energies. Tentative models of the various annealing stages over the range 150°-800° C. were proposed. It was suggested during discussion that the interpretation of these experiments would be far more definite if in the first instance the energy of the bombarding electrons was confined to a value just above threshold (say, 0.5 MeV.), so that only one predominant type of defect was produced, namely, close vacancy-interstitial pairs. The number of possible activation-energies required to interpret the annealing data would then be a minimum and the significance of the present results, obtained at bombarding energy up to 2 MeV., could be more fully appreciated.

A two-phonon process was suggested by J. R. Hardy and S. Smith (Reading) to account for specimen-independent absorption between 3.75 and 7.5 μ . It confirmed that long-range forces are far less important in diamond than in silicon or germanium. Phonons and also excitons were invoked by F. C. Champion and J. Male (London) to explain specimen-independent broad bands in the luminescent excitation spectrum of all types of diamond except type IIb at energies greater than 5.45 eV., but bands at 5.25, 5.36 and 5.39 were attributed to some defect other than nitrogen.

J. Male and J. R. Prior (London) also reported the first examples of fluorescent emission in the ultra-violet from diamond at energies near 5.1 and 5.3 eV.

The growing interest in silicon carbide was shown by four papers on practical aspects involving various mechanical properties such as friction and wear of diamond and silicon carbide, by C. Brookes, by D. R. Miller, by L. M. Fitzgerald and by F. Field and N. L. Hancox, all from Cambridge. The steady improvement in the purity control of silicon carbide was described by W. F. Knippenberg (Holland). Using as starting material cubic silicon carbide prepared by decomposition of chlorosilanes, the total content of foreign atoms, which were mostly chlorine, could be reduced to less than 10^{16} cm.⁻³. Using such pure material, H. Daal, W. Knippenberg and J. D. Wassher measured the Hall constant and the resistance of silicon carbide from 80° to 1,400° K. Much lattice imperfection is indicated since the number of acceptors and donors exceeds the number of chemical impurities by an order of magnitude. Occupying as it does a key intermediate position between silicon and diamond, all the properties of silicon carbide are of great interest and importance. However, because of the different possible atomic arrangements such as cubic and such polytypes as 4H and 6H in the hexagonal form, the interpretation of the optical and electrical properties of silicon carbide is complex. D. Hamilton, W. J. Choyke and L. Patrick (United States) have examined the optical absorption and photoluminescence of 4H silicon carbide, extending earlier work on the 6H polytype. A characteristic edge luminescence was observed in the pure 4H crystals and parts of the spectrum were found to have photon energies greater than the energy gap of polytype 6H. Corresponding absorption experiments showed that the 4H energy gap exceeds the 6H energy gap by 0.25 eV. The transitions are indirect and exciton absorption is observed.

The impression gained from the Conference was that although diamond physics is still in its infancy, sufficient experiments have now been performed over a wide range of properties and techniques to indicate that a relatively few well-chosen experiments, such as the investigation of radiation damage close to the threshold energy, should throw real light on fundamental problems in solid state physics. As Prof. R. W. Ditchburn pointed out at the beginning of the Conference, the unique property of diamond is its stability and the simplicity of its composition. These striking advantages compared, for example, with the alkali halides, as set out in a conference on crystal luminescence held two weeks earlier in Turin, seem to me far to outweigh the relative intractability of diamond as a material in that it prevents the overwhelming flood of experimental data which would undoubtedly ensue if simple methods of 'doping' diamond were available. Diamond physics is on an orderly march which should lead to a real advance in our understanding of solid state physics.

Advantage was taken of the opportunity provided by the Conference to present the Duddell Medal to Prof. R. V. Jones, who then spoke on some developments of the optical lever. In an excellent lecture, enjoyed by all, Prof. Jones described in particular the development of the optical lever in the past ten years up to the present stage when the performance approaches the limit set by the statistical fluctuations of photons in the light beam. Applications covered the evaluation of the thermal fluctuation limit for galvanometers, the detection of the change of linear momentum in a beam of light after refraction, and the development of a sensitive infra-red detector based on linear thermal expansion. The method failed to detect any deviation of a beam of light in an inhomogeneous transverse magnetic field of mean value 8,000 oersteds, although a change in the velocity of light of about 70 μ sec.⁻¹ should have given a deviation equal to the r.m.s. error.

F. C. CHAMPION

THERMAL MOTION IN CRYSTALS AND MOLECULES

THE fifth international congress of the International Union of Crystallography which was held recently in Cambridge was followed by two symposia, one of which was devoted to papers on Thermal Motion in Crystals and Molecules. This symposium lasted for two days, August 22-23, apart from an introductory lecture which was given during the main congress in the previous week. It consisted of five invited papers and thirty other contributions, abstracts of which had been published in advance of the meeting by the International Union of Crystallography.

In the early days of crystallographic studies by X-ray diffraction techniques, thermal motion was a disturbing factor for which rather empirical correction had to be made, by means of the familiar Debye-Waller theory, before the crystallographer could make a crucial comparison of his experimental intensity results with deductions from any postulated structural model. Since then the increasing accuracy of measurements and ease of interpretation have permitted the process to be largely reversed and experiment now allows a detailed assessment of

atomic motions to be made and analysed into various types of vibration. Investigators are no longer restricted to the use of X-rays for electrons, and neutrons are now being widely used in support. Moreover, further theoretical work on the various scattering processes and improvements in experimental techniques have played their parts in increasing the interest in this field of work. During the past few years it is particularly noteworthy that rather empirical descriptions of atomic motions are being superseded by much more comprehensive descriptions of co-operative motions of molecules and crystals as a whole. To a considerable extent, interest has been fostered by the increasing availability of computing machines and programmes able to analyse the experimental results in terms of the many parameters needed for a full description of thermal motion.

Although receptive of any aspect of thermal motion in crystals and molecules, the symposium was aimed at providing discussion of three particular topics: first, the study of the elastic and inelastic scattering of X-rays and neutrons by solids, as a

source of information on the amplitudes and frequencies of motion in crystals and their dependence on temperature; secondly, the use of electron diffraction measurements to study molecular motion in gases; and thirdly, data on residual motion in crystals at low temperatures. The introductory lecture by Prof. J. C. Slater served as a general lecture to the whole congress and was entitled "The Interaction of Mechanical and Electromagnetic Waves in Crystals". While summarizing the more conventional aspects of the scattering of radiation by phonons in crystals, this lecture surveyed the interactions over a very wide range of frequency, and included an account of recent work on the explanation of ferroelectric transitions from the point of view of lattice dynamics. The treatment of Cochran, whereby a ferroelectric transition is emphasized as being a limit of stability against a particular mode of vibration, was shown as a development of the much earlier work of Huang and others on anomalous dispersion in the infra-red region, where a transverse electromagnetic wave interacts with transverse mechanical oscillations in a crystal.

The main symposium began with an invited paper by Dr. D. W. J. Cruickshank, who discussed, chiefly from a theoretical point of view, the determination of atomic vibration amplitudes from X-ray diffraction data, particularly in molecular crystals where the motions are anisotropic. For each atom a vibration tensor with six components can be deduced and these tensors can then be combined to give a picture of both rigid-body vibrations of the molecule as a whole and of internal vibrations within the molecule. At room temperature the latter are relatively small, but they become of greater importance as the temperature is reduced. It was emphasized that X-ray diffraction data alone are not sufficient to give an unambiguous solution, and it is necessary to employ spectroscopic evidence as well in order to distinguish, for example, between internal twisting vibrations and angular oscillations as a rigid body. Investigations concerning the perchlorate ion in perchloric acid monohydrate ($\text{H}_2\text{O} \cdot \text{ClO}_4$) and of ethane were described as examples of the essential part played by spectroscopic data in the analysis of the various motions. The following, complementary, paper by Dame Kathleen Lonsdale surveyed the problems from a more practical point of view in the light of much experimental information accumulated by the author and her colleagues at University College, London. In practice, before true thermal vibrations can be studied, allowance has to be made for zero-point energy, structural disorder and bonding anisotropy. Measurements at reduced temperature and parallel studies with X-rays and neutrons may be necessary in order to secure unequivocal results. The partition of the total thermal motion among internal and rigid-body vibrations was discussed, taking urea, hexamine, naphthalene and anthracene as examples. In the latter case where the directions of the principal axes of atomic vibration are not fixed by crystal symmetry, wide discrepancies in their specification from different, seemingly accurate, sets of results were found. It would seem to be well established that there is still a considerable need for data with improved accuracy, more free from both random and systematic errors, if the detailed conclusions which are drawn from structural analyses of this type are to be justified.

These two general review papers were followed by several descriptions of structural analyses which

depended on the principles previously enunciated, illustrating in the main the relation between atomic motion and the environment of an atom, both within its own molecule and among its neighbours, and with some attention being directed to developments of experimental technique. Increasing attention is certainly being given to measurements at low temperature, but there are still only a few substances for which a detailed analysis has been made at more than one temperature. The value of supporting evidence from other physical methods of analysis, such as specific heats, nuclear magnetic resonance and spectroscopy, is very great.

Both Dr. Cruickshank and Dame Kathleen Lonsdale referred to the information on molecular motion which could be obtained from work on the diffuse inelastic scattering, as distinct from the elastic Bragg peaks, and this theme was taken up in more detail by later contributors. Papers by Dr. W. Cochran and Prof. W. Hoppe described the theoretical calculation of the diffuse scattering from molecular crystals, pointing out the relative significances of the displacements due to translation and rotational motion, and distinguishing between the enhancement of diffuse scattering in the neighbourhood of reciprocal lattice points and that over extended areas. Several succeeding contributions described the experimental verification of these ideas and their value in structure determination. A paper by Dr. M. L. Canut illustrated how experimental measurements of the shape and location of the extended regions of diffuse scattering were in good agreement with calculations made from the shape and orientation of the molecules for substances such as hexamine, pentaerythritol and naphthalene. A related contribution from Drs. E. Sandor and W. A. Wooster emphasized that the detailed interpretation of the diffuse scattering might be carried out accurately enough to be of value in structure analysis. Particularly for planar molecules, the orientation in the structure of a molecule of known shape could be predicted and a molecular Patterson function could be calculated.

In a group of papers on electron diffraction work on gases, it was evident that the greatly increased experimental accuracy which can now be attained has stimulated interest in more detailed work on the diffraction process and the force fields in molecules. Prof. Y. Morino discussed the exact relation of the experimentally determined quantities—the mean atomic distance and the mean square vibration amplitudes—to the actual equilibrium distance and the detailed molecular field. Prof. O. Bastiansen and his colleagues showed that certain linear molecules may appear to be bent on account of vibrations perpendicular to the bond, because the longer interatomic distances within the molecule appear to be shorter than expected from a summation of observed bond distances. Carbon suboxide was shown to be a case where it is difficult to distinguish between a linear molecule with large out-of-line vibrations and a bent equilibrium configuration. One was impressed by recent improvements in experimental techniques; for example, K. Hedberg described how it was now possible to measure the increase with temperature of the vibration amplitudes in phosphorus trichloride, in fair agreement with predictions from spectroscopic data. In discussions of these electron diffraction papers, attention was directed to the importance of using complex scattering factors, reliable values of which are now becoming known and listed.

The influence of atomic vibrations on measured values of lengths of bonds is not, of course, limited to electron diffraction work, and a paper by H. Levy discussed this problem in relation to precise structure refinements by X-ray and neutron diffraction methods. It was shown how the apparent interatomic distance for a pair of atoms depended on whether or not their individual thermal motions were linked or independent. Any attempt to deduce the equilibrium distance of separation, as distinct from the centroid separation, depends on reaching a precise knowledge of the atomic vibrations after making measurements at various temperatures, followed by an extrapolation and allowance for zero point motion. In discussion it was made clear that whenever corrected distances are given it is very essential to specify on what assumptions the corrections have been made. The effects are of particular importance when the motions of hydrogen atoms are being considered and are of especial interest in work on neutron diffraction. This paper, in fact, formed part of a session which was devoted to the contribution of neutron methods to our knowledge of thermal motion, which Dr. W. Cochran opened with a discussion of the great value of measurements of energy distributions of scattered neutrons in a review of recent work on lattice dynamics by neutron spectroscopy at Chalk River. Of particular interest were an extensive series of precise measurements of the dispersion relation, between frequency and wave-number, for the acoustic vibrations in single crystals of lead. In order to interpret the results it is necessary to assume that long-range forces are important in the solid and it is shown that their range becomes less as the temperature is increased. From the widths of the peaks in the neutron-energy spectrum it is possible to deduce the life-time of the phonon vibrations. In a further comprehensive set of measurements the lattice dynamics of the alkali halides and of lithium hydride were investigated. As an example of the contribution of neutron methods to disentangling the effects of thermal vibration and bond anisotropy, a paper given by Dr. R. S. Calder described concurrent neutron and X-ray work on lithium hydride.

In the final session of the symposium, Prof. I. Waller described some recent theoretical work on the frequency distribution and dispersion relations for alkali halides at low temperatures, with particular reference to the approximations which have been made in calculating the form of the zero-point energy vibration amplitudes. The conclusions are in good agreement with results of diffraction experiments. In an interesting survey of a wide range of experimental data, F. H. Herbstein examined the values of

Debye temperature determined for cubic crystals by methods such as specific heat and elastic constant measurement, as well as by diffraction studies at one or several temperatures. At room temperature there is reasonable agreement between different methods, but at low temperatures such meagre X-ray data as exist suggest that the apparent θ values may be lower than those found by other methods. It would seem that some accurate and comprehensive X-ray work in this field would be rewarding.

Two papers were given on the contribution of nuclear magnetic resonance to studying thermal motion. In a review of this application, Prof. E. R. Andrew emphasized that whereas previous speakers had been concerned solely with 'vibrations', there were other forms of motion, such as hindered rotation and self-diffusion, which only occurred infrequently—though involving much greater movements—and which could not be examined by diffraction techniques. Examples were given of how these topics can be investigated quantitatively by nuclear magnetic resonance techniques and how the postulated effects on the spectrum can also be demonstrated by absorption measurements with rotating crystals. Dr. J. A. S. Smith described an application of nuclear magnetic resonance methods to the examination of single crystals of urea and thiourea which demonstrated the onset of hindered rotation about the C=O and C=S bonds in the two cases. As a result the molecules flip between two possible equilibrium configurations, giving rise to large apparent temperature factors for some of the atoms as judged by X-ray diffraction work.

In conclusion, it may be worth recording two personal impressions which remain from the papers and discussions. First, although the precision of experimental measurements in these investigations is very high, there still remain some significant gaps in interpretation which leave room for systematic errors and may make some of the apparent accuracy illusory. Secondly, in spite of the increasing identity of equipment used over the world, one can still be struck by the individuality of thought and methods of approach which characterizes the different schools of investigators.

The symposium was attended by about 400 persons, mainly accommodated in the large lecture theatre of the Arts School at Cambridge, but with an overflow in the adjoining Cavendish Laboratory served by a closed-circuit television set. It was perhaps significant that even for the less-crowded sessions there were many who preferred the quieter, airy contemplation of the television screen to the hurly-burly of the lecture room.

G. E. BACON

THE INTERNATIONAL SCIENTIFIC FILM ASSOCIATION

THE fourteenth annual congress of the International Scientific Film Association was held in Prague during September 16–24. It was attended by 120 delegates and observers from twenty-four countries. The British delegation of twenty people was led by Mr. Edgar Anstey, president of the Scientific Film Association. Associated with the congress was the Third Festival of Films presenting Science.

The International Scientific Film Association is a non-profit-making and non-governmental organization,

officially recognized for consultative status with Unesco. Membership is open to any organization representative of the science film movement in the country of that organization.

The congress were welcomed officially by the Czechoslovak Minister of Education and Culture, Dr. Frantisek Kahuda, and by the managing director of Czechoslovak Film, Mr. Alois Polednak.

The Czech Organizing Committee—led by Dr. Vladimir Vachek—provided a delightful centre in

the form of the Film Club, at which members of the congress could meet and also dine and drink until the early hours of the morning. They also provided facilities for many visits in their beautiful city of Prague, and opportunities for meeting film makers and scientists in their studios and laboratories. The social life was full and active.

The first International Library for Scientific Film is to be set up in Brussels. It is the result of an agreement between the International Scientific Film Association and the Belgian Institut National du Cinéma Scientifique. There has been much discussion over this film library, and the stage has now been reached where the final documents are likely to be signed sometime in 1961. Van den Borre, director-general of the Belgian Ministry of Education, expressed to the general assembly his Government's keen determination to see the project through, and gave some details of financial support. The main tasks of the Library will be to gather together and keep copies of the best scientific films, to classify them, to publish general and specialized catalogues, to organize congresses, and to arrange special showings of films.

Because cinema and television are rapidly becoming closely linked, resulting in many new problems and possibilities for scientific film makers and users, it was agreed to set up a commission to study television in relation to the aims of the scientific film.

Unesco has suggested a study be made on the provision of films in the natural sciences for use in high-schools in newly developing countries. The International Scientific Film Association has been asked to undertake the research, and a commission was set up for this.

Closer co-operation between the Association and specialized international bodies and associations having film sections, for example, the World Veterinary Association, is to be secured by making provision for observers from these bodies to attend Association's congresses.

Greece and Israel were admitted to full membership of the Association, bringing the number of member countries to twenty-eight. It is expected that next year the American Science Film Association is likely to become a member.

The annual congress provides the main discussion opportunity for international science film makers. To meet their needs, there are three sections, each having its own programme of work. They engage in a vast range of activities.

In the Research Section, 11 lectures and 35 reports were delivered, and 68 specialized films were shown. In the Education Section, 4 lectures and 24 reports were made and 62 films were shown. In the Popular Science Section, there was a major discussion on definition of popular science films, two reports were made, and 72 films were shown. In addition, the Popular Science Section organized for the first time three special meetings of television workers from different countries at which ten TV films were shown.

Two B.B.C. producers—Aubrey Singer and James McCloy—presented a clear picture of what was being done in B.B.C. television, and the B.B.C. won much praise for its co-operation in making available a large amount of TV recording.

The question of definition has very much bogged down discussion in the past, and for the first time this year it was felt that the beginning of a successful solution to this problem had been made. In the Popular Science Section, a paper entitled "Types and Genres of Popular Science Films" was read by

Mr. Igor Vassilkov (U.S.S.R.). He divided popular science films into two groups—the didactic and the imaginative—and then used the terminology of literature, because the film has as yet developed no comparable language, to describe the different kinds of films to be found within each category. It was agreed that the nature of such a film is determined by what the writer and director have set out to do. There was long discussion on this paper, in which the writer of this report found general acceptance for his view that the didactic film was now being taken over by TV and specially-made educational films, and that the future for the popular science film lay with the imaginative type of film. It was no longer necessary to popularize science among young people, but to stir their imagination with an understanding of the social implications of scientific development. It was mainly an older generation who had not been taught science at school, who still required the didactic type of popular science film.

The Popular Science Section has agreed to ask member countries to provide details of all the films already made or which will have been finished before January 1, 1961, concerned with the history of science and technology, or of the lives of eminent personalities in science and technology whose discoveries and inventions are of international significance. It will form the basis for a comprehensive catalogue to be published by the Russian branch of the Association.

Among problems that concerned the Education Section was the role of the film in speeding up the rate of learning, that is, to increase the amount learned without increasing the time spent in school. Mr. Vitali Jemtchujni (U.S.S.R.) gave details of a series of new teaching films in physics which were being prepared for production in his country and which were part of an overall attempt to find a solution to this urgent problem.

The Research Section considered films in medicine, biology and botany. Two Russian papers that aroused particular interest were on new Soviet equipment for high-speed still photography and cinematography, and the use of high-speed and ultra-speed filming of technological processes pertaining to agricultural machinery. The latter work has risen from problems caused by the mechanization of cotton harvesting. Film was used to obtain a picture of what happens in separating cotton lobes from the bolls when cotton is picked with pneumatic harvesters. It was claimed that economies in picking and an increase of production resulted from the application of these studies.

The general assembly agreed to award diplomas to the following films shown during the Festival: "The Mountain Canal" (China); "Passport to Space" (Czechoslovakia); "Sea Dancers" (France); "The Magic Tape" (German Federal Republic); "Living Traps" (Hungary); "Morning Sun" (Japan); "Sources of Energy in the Blood Circulatory System" (Poland); "The Revealing Eye" (Great Britain); and "Atomic Ice-Breaker" (U.S.S.R.).

In addition, "Symphony in Steel" (Japan) was given a special commendation for its use of cinema-scope, as was "Timber" (Bulgaria) for its witty treatment of a static subject.

Mr. Alexandre Zgouridi (U.S.S.R.) was re-elected president of Association, and the vice-presidents are Mr. Edgar Anstey (Great Britain) and Mr. J. Varosieau (The Netherlands); the honorary secretary remains Mr. John Maddison, one of the founders of the Association, who this year wished to resign, but

was persuaded to stay on for another term. Mr. Mohamed Afifi (Morocco) was appointed assistant to the honorary secretary. The honorary treasurer is Dr. Vladimir Vaclavek (Czechoslovakia). The honorary life members remain M. Jean Painlevé (France) and Mr. Jan Korngold (Poland). The editor-in-chief of *Scientific Film*, the journal of the Association, is Mr. Maurice Goldsmith (Great Britain).

The liaison officer of the Association with the International Science Film Library is Mr. Luc

Haesaerts (Belgium); the chairman of the Television Study Commission is Mr. John Maddison, and of the Unesco-International Scientific Film Association Science Films Commission, Mr. Bernard Chibnall (Great Britain). The chairmen of the Standing Committees are: Research, Dr. R. Robineaux (France); Popular Science, Mr. V. Tosi (Italy); and Education, Prof. J. Jacoby (Poland). Next year's Congress is likely to be held in Rabat, Morocco.

MAURICE GOLDSMITH

A BRITISH SOURCE OF NATURAL GAS

THAT in Britain there should be in daily use a supply of natural gas may well surprise many well-informed people. Indeed, it was in 1938 that two discoveries of natural gas in Britain were made, one at Cousland, south-east of Edinburgh, and the other west of Whitby at Eskdale. At that time no commercial outlet existed for these potential supplies and the wells were sealed off for eventual future use. The Cousland discovery has been harnessed by the Scottish Gas Board for the use of Musselburgh, where after being suitably treated it forms part of the gas supply.

Now there comes the news of interest more particularly to the inhabitants of the Whitby district of the actual utilization of the gas from the Eskdale area. The wells are situated in moorland of much natural beauty; but there is no fear that the amenities of that fair land will be impaired by the small surface equipment that marks the source of a sufficient supply of gas to serve a new but sole production unit in the Whitby Gas Works.

Two wells, of some eleven that have been drilled, have proved to be gas producers. These wells have a closed pressure approximating to 2,000 lb. per sq. in., and draw their gas from limestone layers, respectively 4,196 and 4,807 ft. below ground-level. It was only in April this year that these wells were re-opened and now the laying of a 3-in. pipe-line has

been completed. Further, in order to produce from the natural gas, which contains 93-94 per cent of methane and has a calorific value of 1,000 B.T.U. per cu. ft., a final gas for public distribution of 500 B.T.U. per cu. ft., a conversion plant has also been installed.

The conversion process of the gas is known as a reforming process. It consists essentially of the reaction of the natural gas with steam to produce hydrogen and carbon monoxide. It is carried out in special heat-resisting steel tubes which are heated to about 1,100° C. and contain a nickel catalyst. It is then enriched with some cold natural gas, and flue gas from the tube-furnace, fired by natural gas. This is necessary to adjust it to the correct calorific value and density for public distribution.

It is also interesting to note that the gas is of such a freedom from sulphur impurity that in order to ensure that gas supplied to the town should have a distinct odour, equipment for the purpose has been installed, employing tetrahydrothiophen as odorant.

The two wells available have a combined flow-rate up to 4.5 m. cu. ft. per day. Three reformer units have been provided, each having a daily capacity of 625,000 cu. ft.

The plant has been put to work in recent weeks, and the venture is so new that the performance tests have yet to be carried out.

R. J. SARJANT

THE LIBRARY IN SCIENCE AND TECHNOLOGY

OF the papers of scientific interest presented at the annual conference of the Library Association at Scarborough, September 12-16, that of Dr. D. J. Urquhart describing the planning of the National Lending Library for Science and Technology and the ideas and motives behind it is undoubtedly the most important, but some of the other papers should not be overlooked by the scientist and technologist. In his presidential address on September 13, Mr. B. S. Page, librarian of the Brotherton Library, University of Leeds, discussed librarianship as he saw it practised in English universities of the twentieth century, and more particularly the research side of such work. Research, he suggested, in fact determined the extent, and very largely the character, of the collections and greatly influenced every aspect of the work of a university librarian, and Mr. Page emphasized, first, that the librarian and his readers were

members of the same university community, with all it implied, and secondly, that the reader regarded the library less as an amenity than as a necessity; his use of it was regular and professional; normally his work could not proceed without it, and how it operated made an immense difference to the reader's peace of mind and perhaps his hopes for the future. From this Mr. Page argued that because selection had to make the most of very limited resources, buying must be largely related to specific interests which have to be known and understood by the library staff, while at the same time important works had to be acquired for future needs and a close watch kept over special collections and special emphases in general collections. The librarian must be thoroughly equipped to make the most of the potential co-operation of the experts in the teaching departments surrounding him and, pointing out that a university

library is being assembled for generations of scholars, Mr. Page claimed that the quality of library development could do much to make or mar the future welfare and importance of the university.

Mr. Page again emphasized the importance of the personal qualities of the librarian in referring to problems of cataloguing and classification, urging that the schemes to be adopted should not be such as to cause irritation or hindrance to the reader, and, besides putting in a word for the value of browsing among the open shelves as a source of inspiration and insight, he pleaded for imagination as well as knowledge on the part of the librarian and his staff. Techniques, he insisted, were means to an end and the librarian must be prepared to meet his readers on their own ground and to speak their language. Moreover, besides professional techniques, he needed specialized knowledge, experience of research, and the enthusiasm which came of such specialization. The ideals of personal acquaintance with books, personal help to readers, and unselfish devotion to the advancement of knowledge were as valid as when Henry Bradshaw formulated them in 1882.

Mr. M. C. Pottinger's account of libraries in the Soviet Union was of general rather than scientific interest. He commented on the generous provision of reading or study rooms as a common feature of Russian Libraries, and on the claim of the Bibliographical Reference Department, with a staff of about 100, at the Lenin State Library, Moscow, to supply bibliographies on any topic. In a subsequent paper to the conference, Mr. R. G. Surridge referred to the lack of attention to bibliography in libraries in Britain and suggested that a new well-designed Chaucer House, in co-operation with the National Central Library, should provide a comprehensive Bibliographical Department.

Miss L. V. Paulin's paper on "Technical Library Services" described some of the co-operative schemes that had been set up in Manchester, Sheffield, Liverpool and elsewhere in a field where any general co-ordinated policy was completely lacking. Most of the schemes, however, were for large cities where many highly developed libraries were already available and the greatest need was in the counties. The rapid development of adequate libraries in technical colleges provided an opportunity for remedying this position, and Miss Paulin quoted from the Ministry of Education's report on Technical Education of 1956 to indicate the opportunity that existed to build up a really integrated technical library service between the public library and the technical college. The most rural county to tackle the problem so far was Herefordshire, where a County Technical Library service, based on the Herefordshire Technical College, would begin in January 1961, but Northumberland and Durham were already co-operating with a Newcastle scheme, and Middlesex with a West London scheme. The Northamptonshire County Technical Library Service, started in July 1957 and based at Corby Technical College, was already experiencing a large potential demand, while in Hertfordshire a technical library and information service was based on technical colleges and completely integrated with the County Library. This pilot scheme was described in some detail by Miss Paulin, who stressed that such services in the country as a whole must be based on co-operation. The main requirements were receptiveness of mind among members of industrial and com-

mercial firms and an awareness of the value of up-to-date information; a comprehensive, easily accessible collection of books, pamphlets and periodicals in the care of knowledgeable librarians, with the occasional assistance of technologists in dealing with inquiries; and equipment for documentary reproduction.

A following paper, by Dr. H. Coblans, on "International and Local Information", attempted to assess the present structure and likely trends of scientific and technical information services from a survey of a few characteristic countries, such as Switzerland, West Germany, France and Poland. On the international plane there were now signs of a more generous policy towards co-operation, and the International Atomic Energy Agency has created a Division of Scientific and Technical Information which publishes a number of bibliographical tools to implement the Agency's statutory responsibility to further the exchange of information among its member States. Urging caution as to the value of some of the new technical possibilities for transmission of information, such as 'Telex', which admittedly if imaginatively used could transform the effectiveness of information services, Dr. Coblans said that each country should endow and maintain a National Science Library adequately staffed to provide the rapid service that new techniques permit, while international governmental organizations must place their great resources of information fully at the disposal of the national centres. The technical advances, however, involved the obligation to re-think and re-shape some of the British principles of publication, bibliography, abstracting, copying and copyright and inter-library loan. Ultimately this should be done by international discussion and agreement, but national associations, such as the Library Association and the Association of Special Libraries and Information Bureaux, must take the first step.

Dr. Urquhart said that the site of 60 acres at Boston Spa, where it was hoped the first buildings of the new National Lending Library for Science and Technology would be ready at the end of this year, allowed for considerable elasticity in planning, and the present aim was to provide the practitioner in science or technology with all the current literature of the world he might need. They were only trying to obtain the older literature where they had evidence of demand, or where it did not exist in a readily accessible collection, but they were prepared to accept and make available scientific and technological literature of any age. The Library should become fully operational in September 1962, and only then could the extent to which it would be able to meet the demand on its services be measured; at present, however, its collection could provide about 90 per cent of the Russian literature and translation which are requested. Staff was being selected so that collectively it could understand not only the language of science but also the increasing number of national languages in which science was written. It was hoped to transfer the 1,000 tons of literature from London to Yorkshire without closing any service, and although it was expected that some requests would go to the Science Museum Library which should have been sent to Boston Spa, the handling of such requests would be simplified by use of the same type of forms.

Dr. Urquhart said it was not intended to start any large technical information service, but rather to

assist existing services where possible by directing attention to any literature in their fields of which they might otherwise be unaware, though it would be part of the new Library's responsibility to see that attention was given to any gaps in the technical information services which might develop: one such gap had emerged with regard to Russian translations, on which the Library was now spending more than £100,000. Dealing more particularly with the relations of the new Library to the rest of the library system, Dr. Urquhart said that in the near future some of the larger libraries and the special libraries would be invited to notify the Library systematically about new serials or conference proceedings which they decided not to acquire, but for which they might have some future need. On the collecting side they would invite all libraries to let them know of publications in the National Library's field for which they received an embarrassing volume of requests for inter-library loans. By collecting such material the new Library would help the inter-library loan arrangements to work more smoothly, but at present the potential loan demand on the new Library seemed to be increasing, and Dr. Urquhart thought the tendency was likely to continue, particularly because the new Library's loan service would be faster than the existing services. Accordingly, they were very interested in efforts to tune up the inter-library loan system. He thought there was no fundamental reason to prevent evolution of a national inter-library loan form using the prepaid flat-rate system for postage.

Irrespective of its effect on inter-library loan procedure, the existence of the National Lending Library for Science and Technology might well have more

profound effects, such as producing a demand for a national lending library for the humanities, possibly based on the National Central Library. Dr. Urquhart, however, left this for future consideration and referred them to the relations of the new Library with local libraries, emphasizing that the potentialities of the comprehensive collection of scientific literature at Boston Spa could not be fully utilized unless the potential users in each locality could discover what they wanted to read, that is, unless guides to the literature of science were available locally. We needed a form of co-operation in which local libraries would assist potential users to find out what they wanted to read, and the National Lending Library would, if necessary, supply this literature. It was intended that such co-operation would be based on the idea that each partner in the scheme would pay his own expenses, and they had recently written about this idea to every local authority and technical college in the United Kingdom. At present, however, standards of technical library service available to the public in many areas were not high: a standard which technologists might criticize as inadequate was attained by only eighteen public libraries and seventeen technical college libraries, and in consequence the National Library was building up some sets of bibliographical tools to lend to libraries which are considering developing their bibliographical collections. They had also been thinking about relations with the public libraries and about the training of librarians, and in conclusion Dr. Urquhart urged that future policy must be based on the scientific analysis of the facts.

CHEMICAL DOCUMENTATION

CHEMISTS nowadays are increasingly eager to receive new chemical matter "hot from the press" but many find it impossible to cope quickly with the mass of information contained in the many traditional journals appearing almost hourly. A few years ago the Chemical Society made a great effort to save the chemist's time by introducing a monthly publication, *Current Chemical Papers*, in which some hundreds of selected titles of papers taken from more than four hundred chemical journals of note were set down under their appropriate sections. The undoubted success of *Current Chemical Papers* has led the American Chemical Society to copy the essentials of the scheme with the publication on an experimental basis of *Chemical Titles**.

The major difference is that *Chemical Titles* is produced by machines and thus may claim a potential wider coverage and give greater detail.

The titles of some five hundred journals, translated where necessary, are punched on to I.B.M. cards together with the authors' names and journal references and are then fed to computers. Within two hours the new journal appears containing three parts. The first part consists of a permuted title index in which key-words from each title have been arranged alphabetically down the centre line of the column. The second part consists of an alphabetical list of

first listed authors together with the titles of their current papers published in the selected journals. The third part (in No. 2 only) gives an index of authors other than the first listed for each paper along with the code reference for the paper.

In addition to the key-word, each horizontal line contains as much of the remainder of the title as the machine's programme permits and thus assists in selection of significant titles.

The system is used by scanning vertically the alphabetical key-word list and then, when interest is seized, by reading the horizontal text. When more information is required the reference code on the right-hand side of the entry is noted and located in the alphabetical author index.

The whole system of making the reference code, etc., and for using the system are described fully in the introduction. It is a very clever and easily understood system which appears to work.

The contents of some 550 journals have been dealt with, and it is planned to make a semi-monthly issue of 2,000-3,000 titles.

A good many improvements have been made in No. 2, especially in editing, and more will be made as experiments proceed and as suggestions and criticisms are received. The printing will need to be much better and larger if possible.

The publication fully justifies the claim that it increases "current awareness". It will probably be of

* *Chemical Titles* No. 1, April 1960, 101 pp.; No. 2, May 1960, 89 pp. Chem. Abs. Service, American Chemical Society

particular value to the industrial chemist anxious to keep "right up to date on the literature".

The course of such an experimental system will be watched with great interest. Its eventual success may well depend on the cost of its production and it

remains to be seen whether American machines directed by Malcolm Dyson can do a cheaper and more useful job for chemical documentation than is being done at present by the carefully selective man- and woman-power behind *Current Chemical Papers*. M. STACEY

MEASUREMENT AND CONTROL OF MOIRÉ FRINGES

THE illustrated booklet "Moiré Fringes for Measurement and Control", prepared by the National Physical Laboratory and the National Engineering Laboratory for members of the machine-tool and engineering industries, gives a brief account of the essential features of moiré-fringe methods and some of their engineering applications (Pp. 11. London: Department of Scientific and Industrial Research, 1960).

Moiré fringes are the pattern of relatively broad equidistant bands produced when two gratings with equal-line spacings are placed face to face, but with the sets of lines not quite parallel to each other. When one of the gratings is moved in the direction at right angles to the lines on it, the fringes move through exactly one fringe spacing as the fringe moves through one grating-line spacing. The variation in brightness as the fringe moves can be detected by a photoelectric cell and the linear movement can therefore be converted into a corresponding electrical signal. Gratings can be produced with radial lines also and thus angular movement can be measured or recorded electrically. Methods for the production of gratings at a reasonable price in the quantities and sizes for industrial use have recently been developed, and copies of master gratings produced at the National Physical Laboratory and National Engineering Laboratory are now available commercially. For most engineering applications gratings with about 1,000 lines per inch are required, but gratings up to

10 in. long with up to 10,000 lines per inch or even glass gratings up to 3 ft. long for special purposes can be produced.

Since moiré fringes are produced by very many accurately spaced grating lines and the effect of any errors of spacing of individual lines is reduced by the averaging process which occurs in the production of fringes, great accuracy in measurement is obtainable by using the fringes. Both analogue and digital systems can be used to handle the photoelectric signals, and various applications related to the automatic positioning of machine tools are described in the booklet. It is emphasized that the successful use of moiré-fringe systems requires specialized optical and electronic techniques and that to obtain maximum advantage from the use of moiré fringes in the machine tool field, close co-operation is required between the mechanical engineer and optical and electronic experts. Future developments of the application of the moiré-fringe technique may revolutionize the design of machine tools and the accuracy of their products.

The secondment of members of the staffs of industrial firms to the National Physical Laboratory and National Engineering Laboratory would be a particularly valuable way of speeding up progress, and the laboratories extend, in the booklet, an invitation to firms with electronic, optical or engineering interests to work with them on projects of mutual interest.

GRAFT VERSUS HOST REACTIONS ON THE CHORIOALLANTOIC MEMBRANE OF THE CHICK EMBRYO

By SIR MACFARLANE BURNET, O.M., F.R.S., and DEBORAH BURNET

Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

THE clonal selection theory of immunity¹ in its present form postulates that in the normal animal a large proportion (perhaps all) of the mesenchymal cells could be divided into clones, each of which is pre-adapted to react with one or other of two antigenic determinant patterns. (The alternatives of being able to react with one, three or four such determinants have not yet been excluded.) The initial distribution of these reactivities is essentially at random, and in the present context there is no call to discuss how the patterns have arisen or how this random distribution to the ancestors of the marked clones could be accomplished. By hypothesis, in the adult there are no clones which can react with normal accessible components of the individual concerned, but there are present clones representing

all types of antigenic determinant not present in the body.

Antibody production is presumed to occur in two phases corresponding (1) to the inductive phase and (2) to the productive phase of orthodox immunological theory. In the inductive phase two processes occur: there is proliferation of the clone to produce many more members and the newly produced cells have an increased reactivity with the corresponding antigenic determinant. In the second phase, renewed contact with the antigenic determinant results in proliferation, conversion to the plasma cell form and production of antibody.

According to orthodox immunological theory (for example, ref. 2), the interpretation of the secondary productive phase is not significantly different

from one based on clonal selection. For quantitative experiments on antibody production, it is almost obligatory to use the secondary phase simply in order to have an adequate concentration of antibody. No possibility, therefore, exists of differentiating directly between the two theories by any experiments in which serum antibody is measured.

For the inductive phase, we have two very different conceptions. On the 'instructive' Landsteiner-Pauling theory the period is occupied by the entry of antigen into macrophages, its conversion into a template form and its transfer to plasma cells in one form or another. On the clonal selection theory the inductive period represents the time needed for stimulated cells of pre-existent clones to multiply to a detectable level and in the process increase their reactivity so as to respond by antibody production to a new stimulus.

To differentiate between the two theories we need to find a technique by which it can be shown that a given population of normal lymphoid cells is either: (a) uniform or nearly so in its immunological potentialities, or (b) contains a minute proportion of cells differentiable from the rest by their ability to react with a definable antigen.

One could establish an 'instructive' theory by showing that, no matter how small the number of lymphoid cells taken, antibody could be produced or some other definable immunological competence demonstrated against a range of antigens.

To establish a selective theory, we need the equivalent of a plating method. If we are looking for a mutant (or a contaminant) present in a bacterial culture in a proportion of 10^{-4} , the only way to detect it is to plate the culture on some medium so chosen that the normal form gives no evidence of its existence while the mutant or contaminant discloses its presence by forming a colony. Colony counts on a series of normal and differential media will allow a quantitative analysis of the different clones in any bacterial culture.

In the method we have devised for studying the Simonsen phenomenon³ on the chorioallantoic membrane^{4,5}, we have something closely resembling a plating method. Briefly, blood or separated leucocytes from a normal fowl is inoculated in 0.1 ml. amount corresponding to about 5×10^4 leucocytes on to the dropped chorioallantoic membranes of 12-day chick embryos. When examined four days later, discrete focal lesions, in number usually between 10 and 100, and with a general resemblance to viral lesions such as those produced by herpes simplex, are observed.

Our own experience is in line with Terasaki's⁶ finding that the cells responsible for the Simonsen phenomenon judged by splenic enlargement after intravenous inoculation are lymphocytes. His estimate that the minimum effective dose is of the order of 10^4 lymphocytes also agrees with our estimate of 2×10^4 leucocytes per chorioallantoic focus.

To be effective leucocytes must be from an immunologically mature bird; embryonic blood or spleen is inert. Further, when the donor of leucocytes and test embryos are from the same pure line, a high proportion of membranes show no foci. By analogy with a wide variety of similar quantitative methods, it can be assumed that each focus is induced by a single cell and that basically it is initiated by an immunologically competent cell which either possesses or can acquire specific reactivity against a foreign antigenic determinant in the chick embryo.

Table 1. TITRATION RESULTS USED FOR FIGS. 1 AND 2

Donor	Foci on substrain (1) membranes	Adjustment
4318 1*	0 0 0 0 0	—
2*	8 2 1 1 1 0 0 0 0 0 0	$\times 2$
3763 1	57 33 5 4 4 1 1 1 0	$\times 1.1$
2	120 100 90 88 86 82 78 75 75 57 52 40 34	$\times 0.62$
	20 15 10 8 1 1 1 0 0	
3	34 34 33 31 30 20 15 8 7 7 1 0 0 0 0	$\times 1.5$

* Counts on random membranes inoculated in parallel included
4318 (1) 40 35 30 19 (2) 36 35 26 22

Through the co-operation of Dr. J. M. Rendell and Dr. J. A. Morris, we have had an opportunity of using two relatively pure-line stocks of White Leghorns maintained at the Werribee Poultry Research Section of the Commonwealth Scientific and Industrial Research Organization. Most of the experimental work in 1959-60 was done with substrains (1) and (2) of their B1 line. As many workers have found, pure-line eggs tend to show a low proportion of fully viable embryos, and we have had to deal with smaller groups than we would like; but the trend of results has been quite consistent.

From a preliminary survey of results when cells from the present fowls were tested on embryos of the same group, it was clear that a large proportion of membranes showed zero or very low counts from inocula producing normal numbers of foci on unrelated embryos. Two birds of group (1), the cock 4318 used for fertilization (by artificial insemination) of the whole group and one of the hens 3763, were chosen for more detailed examination. The results are shown in Table 1. It is clear that the pattern of counts differs, 4318 producing few or no foci on all membranes, while 3763 in each experiment gave a conspicuous group of high counts as well as a large number of zero or very low counts. In order to allow consolidation of the whole series in one figure, the three experiments with 3763 were brought into conformity by taking the level of the 'high sequence' as 45, 80 and 33 respectively, and adjusting this to 50 by multiplying each observed count by the appropriate factor (1.1, 0.62, 1.5).

In the graphs, each adjusted value is shown as a dot and the distribution indicated by the use of a moving aggregate covering five digits on either side of each unit on the abscissae. Ordinates therefore represent the number of embryos showing counts over the range $\pm$ of the value indicated.

In order to provide a model against which the observed distributions can be compared, we have made the preliminary assumption that in our 'pure line' stock (1) we are dealing with two unlinked loci each with three possible alleles ABC and DEF and that antigens ABCDEF are directly related to the corresponding genes. There are probably many other genetic models which could replace this one but it is preferred merely as being simple to handle. By the clonal selection theory each bird will have lymphocytes of those patterns among a, b, c, d, e, f, which correspond to the antigens not present in its cells. If we have a bird of genetic constitution AA/DD, its relevant clones will be of patterns b, c, e and f, while AB/DE will have only c and f. We assume that our flock has come to approach the degree of homozygosity indicated by AA/DD so that although all genes are present the combinations AA and DD are four times and AB and DE twice as frequent as any of the others. If a sire AB/DE covers a flock of such composition one can deduce the distribution of

genotypes among the embryos from eggs he has fertilized. We can also assume that in any given blood sample the proportion of cells in the allowable clones will have some characteristic value not necessarily the same for each clone. By a process of trial and error to find conditions that will fit the observations, we have arbitrarily assigned to our two 'pure-line' donors cock 4318 and hen 3763, the constitutions shown in Table 2. The sort of counts of foci that would be obtained by this hypothesis on embryos sired by 4318 from a flock of the type postulated can be seen from Table 3. On a random set of embryos produced under the conditions mentioned earlier, one can readily calculate the distribution to be expected with these two sets of leucocytes.

3763

Fig. 2

Figs. 1 and 2. Distribution of focal counts when leucocytes from birds shown—4318 (m) and 3763 (f)—were tested on chorioallantoic membranes of the same pure line. Each dot represents one count of the value shown by the abscissae and the line is a moving aggregate to include the number of counts within the range ± 5 of each value. Calc. the results expected from the assumptions described in the text

Table 2. HYPOTHETICAL CONSTITUTION OF DONORS OF LEUCOCYTES

Bird	Genotype	Antigens	Clones and number of cells per 0.1 ml.
4318	AB/DE	ABDE	$\alpha(5) f(1)$
3763	AA/DD	AD	$b(50) c(5) d(5) f(1)$

Table 3. CALCULATED COUNTS OF FOCI ON DIFFERENT EMBRYO GENOTYPES

Embryo genotype	Counts from standard inocula from	
	3763 AA/DD	4318 AB/DE
AA/DD	0	0
AA/DE	5	0
AB/DE	55	0
AB/EF	56	1
BC/EF	61	6

These calculated distributions are compared directly with those observed experimentally in Figs. 1 and 2, which show that by appropriate assumptions it is possible to obtain an excellent agreement between observed and calculated results. The agreement itself is unimportant but the general character of the experimental distribution is unmistakable and significant.

With completion of the laying period of the fowls used in the 1959-60 studies, the birds were divided into pairs and reciprocal skin grafts made. These tests made in collaboration with Dr. J. K. Dineen involved 20 double tests. The overall results were: 6 (15 per cent) rapid rejection, 25 (62.5 per cent) slow rejection and 9 (22.5 per cent) prolonged survival beyond 30 days. This is in accord with the degree of heterozygosity to be expected from the results of the chorioallantoic membrane tests.

The findings so far discussed were made in season 1959-60. With the availability of new-season birds of the next generation, we have now been able to obtain similar patterns of segregation, in groups descended from both substrains (1) and (2) of 1959-60. In one set of tests an unusually large set of eggs of group (2) allowed the use of several embryos of identical parentage. The embryos were all sired by cock 106 on seven of his full sisters, and were tested with leucocytes of the sire and of one of the hens 4442. The results are shown in Table 4. Other tests have shown that patterns similar to those obtained with substrain (1) (3763 and 4318) can be obtained with birds and embryos of the same substrain of the 1960-61 stock. Again as in the previous year when substrain (2) leucocytes are tested on substrain (1) embryos, there is no significant reduction in focal count below that obtained on random embryos. In expressing the results in provisional genetic form, different symbols must therefore be used for the two substrains.

For substrain (2), the symbols PQR may be used for the genes and antigens concerned. If we neglect all low counts, the results in Table 4 can be expressed in terms of 2

Table 4. RESULTS OF TESTS ON INBRED LINE (2), 1960-61 SEASON

Leucocyte donor	Tested on embryos	Focal counts	Random control median count
106 (M)	683 × 106	1, 1, 1, 0, 0	52
"	4385 × 106	4, 2, 1	
"	4525 × 106	150, 123, 0, 0	
4326 (F)	276 × 106	65	70
"	4326 × 106	5, 5, 2, 1, 0	
"	4525 × 106	0	

alleles only—birds 106, 683, 4326 and 4385 can be classed as PP with leucocytes of reactivity *q*, 4525 being PQ and 276 PQ or QQ. Obviously minor interactions also take place, but these need not be elaborated on here.

These findings are in accord with what would be predicted on three assumptions: (a) that preadapted immunologically competent cells, presumably lymphocytes, are present in normal fowl blood and that the immunological patterns they carry correspond to antigenic determinants not present in the donor; (b) that the focal lesions are initiated by an immunological reaction; (c) that tissue antigens in chickens are genetically controlled. Since no immunologist is likely to dispute (b) and (c), the results can be claimed as providing at least *prima facie* support for the clonal selection theory.

If one seeks to interpret the present findings on any other general hypothesis of immunity or antibody formation, the following points seem to be relevant: (1) The histological development of foci suggests strongly that the effective cell initiates the focus, presumably by starting to multiply, within a few hours of lodgment on the chorioallantois. 'Recognition' that the cell is in contact with a foreign antigen is therefore a rapid process. (2) Washed cells are effective so that Jerne's selection theory⁷ cannot be invoked. (3) If the clonal selection theory is not accepted, each effective cell must carry all the necessary information to recognize the foreignness of its surroundings and then develop an immunological reactivity directed against the foreign element.

By appropriate *ad hoc* qualifications it would undoubtedly be possible to describe our findings in terms of an instructive hypothesis of the Landsteiner-Pauling type or of a selection theory by which each mesenchymal cell carried all potentialities of immunological reactivity. The advantage of the clonal selection hypothesis lies simply in the natural fashion with which it covers the results.

The most important points against the clonal view that we have been able to recognize in the present results are: (a) Allowing for a 'plating efficiency', which is probably below unity, the number of foci obtained when by hypothesis only one foreign antigenic determinant is present is sometimes higher than it seems reasonable to expect. (b) Just as many, or more, foci are produced when there can be only one foreign antigen as are obtained on random embryos where there should be several foreign antigenic determinants.

Both findings suggest that the number of cells capable of initiating lesions in response to the antigenic determinants involved is not determined wholly by random processes. We can reasonably hope that with progressive clarification of the immunogenetics of our system, it will become possible to examine in some detail the processes which determine focal counts and by implication the proportion of immunologically competent cells. Irrespective of theories of immunity, the special virtues of the chorioallantoic membrane system can scarcely fail to provide important opportunities to improve understanding of cellular immunology.

DEVELOPMENT OF A SUB-LINE OF MOUSE SARCOMA-180 CAPABLE OF GROWING IN PYRIDOXINE-DEFICIENT ANIMALS

By DR. ENRICO MIHICH and DR. CHARLES A. NICHOL

Department of Experimental Therapeutics, Roswell Park Memorial Institute, Buffalo, New York

THE occurrence of various adaptive processes in populations of neoplastic or bacterial cells is indicated by the tendency of such cells to increase their capacity for growth under adverse conditions. Changes in the growth capacity of neoplastic cells have been associated with the development *in vitro* and *in vivo* of tumour sub-lines resistant to treatment with antimetabolites. Several observations indicate that available antimetabolites of pyridoxine and folic acid do not always duplicate the effects of the nutritional deficiency of these vitamins¹⁻³. In experiments described here, a nutritional depletion of an essential factor *in vivo* has been used, to our knowledge, for the first time as a selective pressure to alter the growth capacity of mammalian cells.

During work on the influence of vitamin deficiencies on experimental tumours in rodents, a high

incidence of complete regression of mouse sarcoma 180 (S-180) following impairment of tumour growth was observed in Swiss mice which were fed a pyridoxine-deficient diet⁴. These observations provided a basis for attempting the selection of a sub-line of S-180 capable of growing in the deficient animals. The development of such a tumour was achieved following repeated transplantations in vitamin B₆-depleted mice.

Mammalian cells cultured in a semi-synthetic medium have a definite requirement for pyridoxine⁵. A similar requirement for the optimal growth of tumours may be indicated by the impaired growth of some induced and transplantable tumours in animals depleted of this vitamin^{4,6-9}. Inhibition of growth and occasional regressions also occurred when, in addition to receiving the deficient diet, the tumour-bearing animals were treated with the pyridoxine

antagonist, 4-deoxypyridoxine¹⁰⁻¹⁵. Experiments were carried out in this laboratory on several transplantable tumours using dietary depletion alone to avoid any non-specific effect which may be associated with treatment with such antagonists. Marked retardation of neoplastic growth was observed in most cases; this effect, however, was transient. In some instances the sensitivity of different hosts to the vitamin deficiency did not permit a selective anti-tumour effect¹⁶. The impairment of *S*-180 in pyridoxine-deficient *HaICR* Swiss mice was striking, however, not only because the growth of the tumour was selectively inhibited, but also because 30-80 per cent of the implanted neoplasms regressed completely after initial growth⁴. Of several thousand compounds tested for activity against *S*-180, a limited number of these depressed the rate of growth of this tumour. Complete resorption of *S*-180 has been observed, however, only after treatment with 6-mercaptopurine and related purine analogues¹⁷. Thus, the regression of this tumour in pyridoxine-deficient animals is of particular interest.

The sub-line of *S*-180, designated *S*-180/*B*₆, was developed over a period of eight months by a gradual increase of the severity of vitamin depletion of the host mice. The standard procedures followed for the implantation of the tumours, the evaluation of tumour growth, and the preparation of the purified diets have been described previously⁴. Tumours were implanted into groups of 3-5 mice. In initial experiments *S*-180 was implanted in mice which were fed the pyridoxine-deficient diet beginning two weeks prior to implantation; this period of dietary depletion has been, in our experience, the minimum one which caused significant effects on the tumour⁴. These neoplasms, however, were invariably lost on two to three repeated transplantations into similarly depleted mice. Further attempts were successful when the period of depletion of the animals in which *S*-180 was to be implanted was prolonged gradually.

The growth of the tumour at different stages during the process of selection is indicated in Fig. 1 by the size of the tumours on the 8th day after implantation. In Fig. 2, progressive rate of growth of successive implants is shown. The sub-line was developed as follows. An 8-day-old *S*-180 tumour (8.3 mm.) grown in mice which were fed a complete diet was transferred

Fig 1 Selection of a sub-line of *S*-180 capable of growing in pyridoxine-deficient mice

Fig. 2. Growth of *S*-180 during the course of successive implantations in pyridoxine-deficient mice

* Serial numbers of transplantation from the beginning of the experiment

to mice fed the deficient diet from the day of implantation. On the 8th day of growth these tumours (7.8 mm.) were implanted in mice which were then fed the deficient diet (transplant No. 3). Eight days later the tumours (8.9 mm.) were implanted in mice fed the deficient diet starting one week prior to implantation. When these tumours were 8-days old (3.7 mm.) they were implanted again in similarly depleted mice (transplant No. 5). The tumour did not grow for 2 weeks (see Fig. 2); during the 3rd week 1 tumour out of 3 grew to a size of 5.4 mm., and this tumour was transferred to mice depleted of pyridoxine for 1 week before implantation. Following the next 5 successive transfers in similarly depleted mice, the tumour reached a size larger than 4.0 mm. in 2 weeks and was transplanted at the end of this period. Growth following transplant No. 11 is shown in Figs. 1 and 2. At this point the rate of growth of the tumour seemed well stabilized, and transplantations into mice fed the deficient diet for 2 weeks prior to implantation were begun. The rate of growth of the tumour increased gradually during the 9 subsequent passages (the size of the tumour was 4.2 mm. 2 weeks after transplant No. 12 and 8.1 mm. 2 weeks after transplant No. 20). From transplantation No. 21 on, the tumour was repeatedly implanted in mice which were fed the deficient diet for 3 weeks prior to implantation. At transplantation No. 23 and thereafter, the tumour reached a size larger than 5.0 mm. in 1 week and was always transplanted at the end of this period (growth following transplantation No. 28 is shown in Fig. 2). Growth was variable in subsequent transplantations (see Fig. 1), but in every instance the tumour, now called *S*-180/*B*₆, maintained its capacity to grow in the deficient mice. This tumour is currently carried in our laboratory in mice fed the pyridoxine-deficient diet beginning 3 weeks prior to implantation and is now in its 125th passage.

Simultaneous transplantations of *S*-180/*B*₆ into the right axilla and of *S*-180 into the left axilla of the same deficient or normal animals were performed at

Table 1. GROWTH OF *S*-180/*B*₆ AND *S*-180 IMPLANTED BILATERALLY IN THE SAME MICE FED A COMPLETE OR A PYRIDOXINE-DEFICIENT DIET*

* The purified diets were fed starting 3 weeks prior to implantation. Ten animals were used in each group. Transplant No. 23 of *S*-180/*B*₆ was used in this experiment.

† The figures shown were derived from the last measurements of the palpable tumours which were taken prior to the death of the animals. The mice fed the complete diet died as a consequence of tumour growth during the 2nd and 3rd week after implantation; those fed the deficient diet died during the 2nd to the 5th week after implantation.

the 28th passage of *S*-180/*B*₆ (Table 1). *S*-180 and *S*-180/*B*₆ implanted bilaterally in animals fed the complete diet, grew at a comparable rate. In contrast, when the two tumours were implanted simultaneously in the same pyridoxine-deficient mice, *S*-180/*B*₆ grew progressively whereas *S*-180 was greatly impaired and regressed in half of the animals. A similar test using 10–30 mice per group was performed at the 23rd, 41st, 57th, 72nd, 81st and 104th passage of *S*-180/*B*₆ with comparable results. Similar differences of growth were observed when the two tumours were implanted in separate mice fed complete or pyridoxine-deficient diets. This observation excluded the possibility of any interference of one tumour on the growth of the other when both of them were implanted bilaterally in the same mice.

The results reported above clearly indicate that *S*-180/*B*₆ is capable of growing progressively in deficient mice in which *S*-180 is greatly impaired. If this adaptation concerns an alteration in metabolism involving pyridoxine, the pertinent biochemical changes would be of particular interest. If, on the other hand, the selection *in vivo* involves the outgrowth of cells less influenced by host defence mechanisms, an opportunity is provided for the study of factors modifying the tumour-host relationship.

Following partial hepatectomy of pyridoxine-deficient rats, the content of vitamin B₆ in the regenerated liver was similar to that of the surgically excised portion of the same organ, suggesting that the vitamin might be transferred to the liver from other tissues¹⁸. Similarly, the adapted tumour might have greater capacity than the parent tumour to bind pyridoxine derivatives. Therefore, the vitamin B₆ content of the two tumours was measured. Both *S*-180 and *S*-180/*B*₆ tumours, grown in deficient hosts, had a similar low content of total vitamin B₆ (Table 2). The striking difference in rate of growth of the two tumours in the same deficient host, despite the similar vitamin content of the two tissues, infers that differences in the efficiency of enzymatic reactions related to growth might occur. Since such differences could be associated with the function of specific forms

of the vitamin, experiments are in progress in collaboration with Dr. James A. Bain of Emory University to measure the content of pyridoxine, pyridoxal, pyridoxamine and their phosphorylated derivatives in *S*-180 and *S*-180/*B*₆.

Although the Swiss mouse is not genetically homogeneous and *S*-180 is not, therefore, truly compatible with this host, this tumour does not normally regress in these animals. Indeed, regressions were not observed even after treatment with compounds capable of depressing markedly the rate of growth of *S*-180^{19,20}. As mentioned previously, regressions of this tumour in Swiss mice following chemotherapy were observed only in animals treated with certain purine analogues¹⁷. The observation that cortisone prevented the regressions of different tumours induced by 6-mercaptopurine suggested that this effect was partially dependent upon host factors²¹. The regression of *S*-180 in Swiss mice depleted of pyridoxine seems also partially dependent on host mechanisms directed against this tumour. Indeed, treatment of the depleted mice with cortisone⁴, and total-body irradiation of the depleted animals prior to tumour implantation²² markedly reduced the incidence of regression of *S*-180. That the Swiss mouse possesses potential defence mechanisms against *S*-180, which can become evident in certain experimental conditions, was suggested, also, by the regression of this tumour in mice treated with 'Zymosan'²³ or infected with BCG (*Bacillus Calmette-Guérin*) as long as two months prior to tumour implantation²⁴. Although the nature of these defence mechanisms has not yet been clarified, the possibility exists that the regression of *S*-180 in Swiss mice depleted of pyridoxine may be, in part, the result of a change in the immunogenetic balance between this tumour and this host. This change might occur either by a change of 'antigenicity' of the tumour, or by some alteration of the host responses to the tumour. Indeed, in either case, the development of *S*-180/*B*₆ may be somewhat similar to the changes in immunogenetic specificity and growth capacity of a tumour which have been observed during growth under various selective pressures²⁵.

The delayed emergence and gradual development of a tumour capable of growing in pyridoxine-depleted hosts is reminiscent of the pattern of growth observed during the development of drug resistance by a transplantable leukaemia²⁶. This analogy suggests the possibility that a similar selection from a mixed population of cells has conditioned the development of *S*-180/*B*₆.

The development of this sub-line of *S*-180 provides experimental material for further study of the contribution of metabolic or immunogenetic factors to the altered growth capacity of a mammalian tissue.

We wish to express our sincere appreciation to Mr. Kalman Bercsenyi for assisting with the transplantation of tumours and to Mr. Robert J. Leonard and Mr. Giorgio Lenaz (visiting medical student, University of Bologna, Italy) for performing the microbial

Table 2. PYRIDOXINE CONTENT OF *S*-180/*B*₆ AND *S*-180 FROM ANIMALS FED COMPLETE AND PYRIDOXINE-DEFICIENT DIETS

Tumour	No. of assays*	Average content of pyridoxine $\pm$ S.D.	
		Complete diet†	Pyridoxine-deficient diet†
		μ gm. per gm. wet weight	
<i>S</i> -180	12	0.86 $\pm$ 0.16	0.17 $\pm$ 0.07
<i>S</i> -180/ <i>B</i> ₆	8	0.78 $\pm$ 0.24	0.14 $\pm$ 0.04
<i>S</i> -180†	1	0.50	0.14
<i>S</i> -180/ <i>B</i> ₆ †	1	0.50	0.12

* For each assay, 5 to 20 tumours of each experimental group were pooled on the 8th day after implantation. The microbial assay (*Saccharomyces carlsbergensis*, ATCC No. 9080) measures the total content of the different forms of vitamin B₆ following acid hydrolysis of the samples. All values are related to pyridoxine as the free base.

† Diets were fed starting 3 weeks prior to implantation.

‡ Tumours were implanted bilaterally in the same animals.

assays. This work was supported, in part, by research grants CY-2857 and CY-4130 from the National Cancer Institute of the United States Public Health Service.

BIOCHEMISTRY OF BOVINE KETOSIS: THE THERAPEUTIC USE OF FUMARATE AND CYSTEAMINE

By DR. S. J. BACH and K. G. HIBBITT

Department of Physiology, University of Bristol

THE principal biochemical symptoms of bovine ketosis are a high level of ketone bodies in the body fluids and a hypoglycaemia of variable severity; a considerably lowered hepatic glycogen-level has also been observed¹. There are reasons for believing that the enforced milk production in the post-parturient animal imposes a severe strain on its carbohydrate and fat metabolism, and that ketosis constitutes an aggravation of this metabolic imbalance.

Suboptimal Reaction-rates in the Citric Acid Cycle. We have shown (ref. 2) that the citrate-level in the serum of ketotic animals is only approximately 20 per cent of the normal. As a working hypothesis, it was suggested that this finding could signify a diminished rate of condensation of acetyl coenzyme A with oxalacetate to form citrate (Fig. 1). In support of this, it will be seen from Fig. 2 that when the citric acid cycle was stimulated by injections of sodium fumarate into ketotic animals, the citrate concentration increased to attain a normal level. One of the principal reasons for such a diminished utilization of acetyl coenzyme A in the cycle was thought to be its competitive use for fat synthesis in the post-parturient animal. In this, at the peak of milk production, the utilization of acetyl coenzyme A for the formation of fat may take preference over that for citrate synthesis (Fig. 1). An over-production of acetyl coenzyme A through activation of large quantities of ruminal fatty acids by coenzyme A would, according to accepted views^{3,4}, lead to excess formation of ketone bodies; another contributing factor may be a diminished supply of reduced pyridine nucleotides (see below). Some evidence for the preferential direction of acetyl coenzyme A towards fat metabolism is provided by the accumulation of coenzyme A in the lactating gland⁵. Attempts were made to shift the equilibrium between the two competitive reactions of acetyl coenzyme A towards the citric acid cycle in the ketotic animal by administering fumarate, which would

stimulate the cycle and, in particular, would provide an extra supply of oxalacetate for the condensation with acetyl coenzyme A. From Fig. 3 it will be seen that this treatment had the expected effect, namely, that the level of the ketone bodies in the serum was considerably reduced.

Although the diversion of the metabolism of acetyl coenzyme A from its oxidative path towards fat synthesis is considered to be one of the general causes of the apparent suboptimal reaction-rate in the cycle, there is also some evidence for an interference with two specific reactions in the cycle, namely, with the oxidation of pyruvate and with that of oxoglutarate (Fig. 1); for we have shown² that in bovine ketosis the levels of both these oxo-acids were several hundred per cent greater than normal and that that of succinate was considerably depressed. The idea of a retarded oxidation of these oxo-acids suggested itself. Both reactions proceed by a common unique mechanism and require the same

Fig. 1 Metabolic pathways relevant to bovine ketosis. Reactions represented by broken lines are believed to occur at suboptimal rates. + + +, in rectangle, elevated serum levels; ---, in rectangle, depressed serum-levels.

co-factors, among them coenzyme A. This, as pointed out above, is used in the post-parturient animal to a great extent for the activation of ruminal fatty acids and is partly lost through milk secretion^{6,7}. These considerations led us to envisage the possibility that the interference with the oxidation of pyruvate and of oxoglutarate in ketosis may be caused by a reduced availability of coenzyme A. The idea is supported by the work of Peeters *et al.*⁸, in which the authors showed a diminished acetylating power of ketotic cows, as ascertained by their excretion of acetylated sulphanilamide. Moreover, Gallagher⁹ has recently demonstrated a subnormal level of coenzyme A in the livers of ewes suffering from ketosis. The above hypothesis was tested by injecting into ketotic animals small quantities of cysteamine, which in certain reactions possesses coenzyme A activity¹⁰. From Fig. 4 it will be seen that this treatment caused a rapid fall in the serum-levels of pyruvate and oxoglutarate. On the other hand, treatment with fumarate proved to be ineffective in this respect, leading to an even greater increase in the levels of pyruvate and oxoglutarate. This was to be expected if one accepted the view that fumarate stimulated the cycle without, however, overcoming the interference with the oxidation of the two oxo-acids.

Both forms of treatment, as shown in Figs. 2 and 3, led to a disappearance of the other abnormal biochemical symptoms investigated—cysteamine treatment more rapidly than fumarate treatment. Among

Fig. 2. Changes in the serum levels of citrate during treatment of cows suffering from ketosis with fumarate (20 gm. in 450 ml. water, injected subcutaneously), —, and cysteamine (750 mgm. in 250 ml. water, injected intravenously), ----.

Fig. 3. Changes in the serum levels of glucose and ketone bodies during treatment of cows suffering from ketosis with fumarate, —, cysteamine, ----. Dosages as in Fig. 2.

Fig. 4. Changes in the serum levels of pyruvate and α -oxoglutarate during treatment of cows suffering from ketosis with fumarate, —; cysteamine, ----. Dosages as in Fig. 2.

the symptoms of recovery was an immediate rise of the abnormally low level of glucose in the serum. These low levels may be caused by an interference with the adenosine triphosphate-requiring *synthetic* mechanism, since in bovine ketosis the *degradation* of glucose appears to be proceeding at a normal rate¹¹. It can therefore be argued that an increase in the formation of adenosine triphosphate through stimulation of the cycle could raise the level of hepatic glycogen and that of blood glucose. Furthermore, with more glucose present for the purpose of degradation, more reduced pyridine nucleotides should become available for the reduction of acetoacetyl coenzyme A, which in turn would lead to a decrease in the level of ketone bodies, since an inverse relationship appears to exist between the degree of anaerobic degradation of carbohydrate and the accumulation of ketone bodies^{12,13}.

Therapeutic Experiments. Of 16 animals treated with sodium fumarate, 14 responded to the treatment and recovered within 7–10 days. All the 33 cases of primary ketosis treated with cysteamine responded rapidly and recovered within 3–6 days. Figs. 2–4 refer to pairs of animals which, for the sake of comparison, were selected for the similarity of the pre-treatment-levels of their serum components. However, the course of recovery shown in these graphs was very similar in all recorded cases, full details of which have been published elsewhere¹⁴.

SELF-DECOMPOSITION OF COMPOUNDS LABELLED
WITH RADIOACTIVE ISOTOPES

By DR. R. J. BAYLY

The Radiochemical Centre, Amersham

AND

DR. H. WEIGEL

Chemistry Department, Royal Holloway College, University of London, Englefield Green, Surrey

IT is quite evident that before an isotopically labelled compound can be profitably used its purity must be known. This will normally be determined following the preparation of the material and, if it is purchased, the information will be provided by the commercial supplier. However, if the material is not used at once, it may undergo significant decomposition under the influence of its own radiation, and there are some aspects of this problem of which we feel users of tracer compounds are insufficiently aware. It is true there is a substantial literature on radiation chemistry generally, but most of it is concerned with irradiation of solutions rather than of pure organic substances, while the actual phenomenon of radiation self-decomposition has been dealt with in relatively few papers¹⁻⁵. The object of this article is to analyse the problem with particular reference to carbohydrates and to present some further quantitative information.

It is important to distinguish in what follows between a chemical and a radiochemical impurity, and to be clear what is meant by the latter. We define a radiochemical impurity as being any radioactive species other than the declared isotope in the stated position(s) of the given compound. In passing, we may note that it commonly happens that a small quantity of radiochemical impurity can be critical whereas a comparable amount of inactive impurity is unimportant.

Types of Self-decomposition

The decomposition of a compound labelled with a radioactive isotope can be due to one or more of four effects:

(i) Primary (internal) radiation effect, that is, the decomposition or transformation of a molecule caused by the disintegration of one of its unstable atomic nuclei. This atom, transformed into another element, might or might not be eliminated from the molecule. However, in either case, providing the daughter nuclei are stable, this will only give rise to a radiochemical impurity if the molecule contains a further radioactive atom.

(ii) Primary (external) radiation effect, that is, the decomposition or transformation of a molecule by interaction with a nuclear particle. If the molecule is a labelled one, this will contribute to the radiochemical impurity.

(iii) Secondary radiation effect, that is, the decomposition or transformation of a molecule of the labelled compound due to its reaction with reactive species, for example, free radicals, produced as a result of primary radiation decomposition. The reactive species may not necessarily be produced from the labelled compound but from its environment, for example, residual water in freeze-dried samples.

(iv) Chemical effect, that is, the decomposition or transformation of the radioactive material caused by chemical reactions which are not connected with radiation. Clearly, this is a hazard faced by any chemical compound, but it may be more probable in the case of a labelled one for several reasons. First, in an effort to obtain a good yield of material of high specific radioactivity, the highest chemical purity is not always achieved, and it is often difficult or expensive to determine this purity. The impurities may then react with the compound. Further, the small amount—possibly only a few micrograms—of radioactive material which is commonly synthesized or distributed by suppliers may suffer chemical decomposition in unexpected ways which would not normally be observed with larger quantities. It could be due, for example, to the atmosphere above a solid, or non-inertness of the container.

Magnitude of the Radiation Effects

The magnitude of the primary (internal) effect can be calculated in any particular case from the available data. Commonly it is a greater practical concern to know the amount of radiochemical impurity produced, and this can be calculated if the pattern of labelling is known. An example of this is given in the subsequent section on macromolecules.

One of the factors influencing the amount of decomposition due to primary (external) and secondary effects is the fraction of its own radiation energy absorbed by the labelled material. For a pure β -emitter distributed over a relatively large area in a layer of even thickness l (cm.) this fraction, F , is given by:

$$F = \frac{pl}{2r} \left(1.5 + \ln \frac{r}{pl} \right)$$

where p is the density (mgm. cm.⁻³) and r is the mean range of the particles, expressed in mgm.cm.⁻² units. In this it is assumed that $r \ll pl$ and that all particles have the energy corresponding to their mean energy. A more exact value may be obtained for definite values of p and l using a known beta-spectrum, but the error is generally small. No allowance is made for back-scatter from the container or for edge effects, though for a given area these latter will, of course, be of increasing significance with increasing energy of the β -particle. The calculation involves determination of the average range of a β -particle by a double integration, the first for the solid angle around a point in a layer of the material, and the second for the contribution of all layers throughout the thickness of the solid.

The magnitude of decomposition (per cent) due to the primary (external) radiation effect is $\{1 - \exp(-F\epsilon a_0 t. 6.14 \times 10^{-16})\} 100$, where F is the fraction of its own radiation energy absorbed by the compound, ϵ is the mean energy of the radiation in electron-volts, a is the number of molecules irreversibly damaged per 100 eV., a_0 is the initial specific radioactivity of the compound in curies/mole, and t is the time in seconds. For compounds labelled with relatively short-lived isotopes, the term t in this expression should, of course, be replaced by $1/\lambda \{1 - \exp(-\lambda t)\}$, where λ is the radioactive decay constant.

Remedial Measures

It is clearly desirable to reduce the magnitude of decomposition of labelled compounds to a minimum. Setting aside the decomposition due to the primary (internal) radiation effect as being beyond control, we can consider the possible remedies for the other three types of decomposition.

Considering decomposition due to the chemical effect first, it is evident that the highest possible degree of freedom from harmful impurities is desirable, consistent with the requirements for specific radioactivity. Storage under vacuum is a common and useful precaution. Attention should also be paid to the inertness of the storage vessels, particularly for liquids or freeze-dried syrups. In our experience the alkalinity of normally washed 'Pyrex' glass is detrimental to the stability of carbon-14 carbohydrate syrups. Storage at as low a temperature as possible can also help by reducing the rate of otherwise unavoidable chemical reactions.

The two fundamental methods for reducing the magnitude of primary (external) radiation decomposition are dispersion over a large area and dilution.

As already pointed out, the fraction of its own radiation energy absorbed by a radioactive compound distributed over a relatively large area is dependent on the thickness and density of the layer. Thus, the principle of such dispersion is to ensure that the nuclear particle escapes from the body of the radioactive material with the minimum interaction on the way. This method has been widely utilized in storage of labelled compounds—particularly for small quantities at high specific radioactivities—but frequently the material may need to be distributed over an area too large to be practical in order to reduce the self-irradiation to a satisfactory level.

The object of dilution is to interpose inactive molecules in the path of the radiation. This can be achieved either by adding the inactive form of the compound itself or by introducing other substances. The former avoids the necessity of subsequent isolation of the radioactive compound, but as it involves a drop in specific radioactivity it is not always acceptable.

It is not possible to suggest a universal method which will prevent the decomposition due to secondary radiation effects. However, it is evident that either dispersion over an area or dilution with the substance itself will reduce this type of decomposition, but the effect of dilution with a foreign substance will depend on the nature of that substance. On the credit side it will absorb radiation which might produce radioactive impurities, and in certain cases it may terminate chain reactions which would otherwise result in substantial decomposition following the radiolysis of a few radioactive molecules^{6,7}. Conversely, if unwisely chosen, it may produce, by interaction with the radiation,

reactive species which will interact with the labelled compound, and so do more harm than good. It is important to appreciate how wide is the range of susceptibilities to radiation for different compounds⁴. Storage of radioactive materials at low temperatures will usually reduce the decomposition due to secondary radiation effects, but will not, in general, completely prevent it. A high standard of chemical purity, already stressed for another reason, may also reduce this decomposition, since, although the impurity may not be harmful in itself, the products of its interaction with the nuclear particles may be. An example of such an impurity is water in the case of carbohydrates.

Observations on Carbon-14 Carbohydrates

The stabilities of samples of uniformly labelled [¹⁴C]-sucrose and D-[¹⁴C] glucose with relatively high specific radioactivities are shown in Table 1. The compounds were prepared by photosynthesis, purified by ion-exchange and paper chromatography and finally crystallized. No radiochemical impurity was detected in either case by reverse isotope dilution analysis, and their chromatographic radiochemical purities were both found to be 99.9 per cent. After being dispensed from aqueous solutions, samples were stored in the freeze-dried form or uniformly distributed on Whatman No. 3 paper. In either case they were contained in 'Pyrex' tubes which had been filled with water and autoclaved for 2 hr. at 15 lb./sq. in. to remove surface alkalinity. The tubes of those samples which were stored *in vacuo* were evacuated to a pressure of 0.01 mm. mercury for several hours before being sealed in order to reduce the moisture content to a minimum.

The radiochemical impurities produced during storage were determined by scanning of paper chromatograms. Spots with R_F values corresponding to those of glucose and fructose were the principal impurities in the case of sucrose.

Many other experiments covering a wide range of specific radioactivities have shown that, under given storage conditions, the amount of decomposition is proportional to the specific radioactivity, provided that the substance is not allowed to decompose too far.

A comparison of tubes 7–10 suggests that, in at least the first three of these, secondary radiation effects take a major role in the decomposition. This is perhaps not surprising, since freeze-dried glucose will retain non-bonded water as 'impurity'. Sucrose, on the other hand, can with efficient freeze-drying techniques be obtained anhydrous, and the small difference in magnitude of decomposition between tubes 1 and 2 suggests that in these cases decomposition is to a great extent due to primary radiation effects. This view is supported by the relatively high calculated value for the apparent energy required to disrupt one molecule (24 eV. for tube 2). By the same criterion the most stable freeze-dried glucose sample (tube 10) is probably still greatly susceptible to decomposition due to secondary radiation effects.

It is clear from the high $G(-M)$ values for tubes 3–6, 11, 12, that such decomposition as does occur when radioactive sugars are distributed on paper is due to secondary radiation effects, probably as a result of the moisture content of the paper. However, under optimum conditions, the overall magnitude of decomposition is markedly reduced by storage under such conditions and so, since it is easy to recover the sugar quantitatively, this method is now used to facilitate

Table 1. SELF-DECOMPOSITION OF [^{14}C]-SUCROSE AND D- ^{14}C] GLUCOSE

Compound	Tube No	Storage conditions			Impurity observed (per cent)	Initial decomposition per year per mc./mM (per cent)	Average mass per unit area (freeze-dried) (mgm./cm. ²)	Area of paper (cm. ²) (d)	Energy absorbed by sugar or sugar syrup ($\bar{E} \times 100$) (per cent) (e)	G(-M) value (f)
		Form	Temp.	Pressure						
Sucrose (a, b)	1	Freeze-dried	Room	Vac	16.4	0.071	0.85	—	16	4.6
	2	Freeze-dried	-80° C.	Vac.	15.1	0.065	0.85	—	16	4.2
	3	On paper	Room	Atm.	15.7	0.068	—	21	0.3	284
	4	On paper	-80° C.	Atm.	4.9	0.020	—	21	0.3	68
	5	On paper	Room	Vac.	2.4	0.010	—	21	0.3	33
	6	On paper	-80° C.	Vac.	1.8	0.007	—	21	0.3	25
Glucose (c)	7	Freeze-dried	Room	Atm.	18.9	0.77	0.2	—	10	79
	8	Freeze-dried	-80° C.	Atm.	6.0	0.23	0.2	—	10	23
	9	Freeze-dried	Room	Vac.	18.1	0.51	0.2	—	10	53
	10	Freeze-dried	-80° C.	Vac.	8.6	0.133	0.2	—	10	14
	11	On paper	Room	Vac.	1.2	0.044	—	47	0.05	900
	12	On paper	-80° C.	Vac.	0.7	0.026	—	47	0.05	526

(a) Each tube of sucrose contained 500 μc in 1.16 mgm. sucrose (149 mc. per m.mole, abundance of carbon-14 19.5 per cent) and was stored for 88 weeks. Calculation shows that primary (internal) radiation decomposition contributed 0.05 per cent to the observed impurity.

(b) Other experiments with samples of freeze-dried sucrose have shown that at -80° C. decomposition is considerably increased if the sugar is stored under atmospheric pressure instead of being sealed under vacuum. The difference is even greater with samples held at room temperature.

(c) Each tube of glucose contained 100 μc in 0.43 mgm. glucose (42 mc. per m.mole; abundance of carbon-14 11.0 per cent) and was stored for 34 weeks. Calculation shows that primary (internal) radiation decomposition contributed 0.005 per cent to the observed impurity.

(d) The weight of the Whatman No. 3 paper was 18 mgm. cm.⁻².

(e) The fraction of the energy absorbed by the sugar or sugar syrup was calculated either (i) by using the relationship deduced above, although the geometry is some way from the ideal; or (ii) by assuming the compound and the paper to absorb all the radiation in the ratio of their weights.

(f) Defined as the number of molecules permanently altered or decomposed per 100 eV. absorbed by the sugar or sugar syrup.

the supply of carbohydrates with high specific radioactivities from the Radiochemical Centre.

An example of the varied decomposition by secondary radiation effects was recently observed by us. [^{14}C]-dextran sulphate containing c. 20 glucose units per molecule was prepared by sulphation of an appropriate [^{14}C]-dextran hydrolysate. It had the relatively low specific radioactivity of 22.4 mc. per gm. atom of carbon (c. 3 mc./m.mole dextran sulphate). It was stored in the freeze-dried form, but when inspected after three weeks it was charred and became a total loss, whereas inactive dextran sulphate did not decompose during storage for several months. The decomposition of the labelled dextran sulphate was presumably due to a secondary radiation effect arising from the prior liberation of sulphuric acid. The sulphuric acid, being fortified rather than diluted in the process, destroyed the rest of the material.

Macromolecules

We quoted earlier an expression for the magnitude of the primary (external) effect which includes a term for specific radioactivity, s_0 , expressed in curies per mole. While it is, of course, true for all compounds, it is particularly important when dealing with macromolecules to appreciate that this term needs to be expressed on a molar, and not on a unit weight, basis. To illustrate this we may consider the case of some glucose, maltose and amylose (containing n glucose units), all prepared from [^{14}C]-carbon dioxide of the same specific radioactivity, and stored under identical conditions, so that the irradiation per unit mass is the same in each case. It is clear that for each destructive interaction between a β -particle and a carbohydrate molecule the impurity produced will contain x , $2x$, and nx atoms of carbon-14 respectively in the three cases. Nevertheless, if we hydrolyse such partially decomposed samples, the resultant glucose will have the same purity in each case, neglecting any effects due to other causes.

How secondary effects will vary with increasing chain-length will depend on what the result of the particular effect is. In some cases the above principle will hold, whereas in others—such as attack on reducing end-groups—it will not.

It is sometimes necessary to consider the contribution of the primary (internal) effect to the production of radiochemical impurity from a labelled macromolecule. This will depend, of course, on the pattern of labelling. For example, in a polysaccharide prepared directly from [^{14}C]-carbon dioxide, so that the labelling is statistically uniform throughout all its molecules, the number of radioactive atoms in the form of an impurity initially produced per nucleus disintegrating is the multiple of its isotopic abundance expressed as a fraction and $(n - 1)$, where n is the number of atoms of the given element in the molecule. Production of radiochemical impurity due to this cause, will, of course, fall exponentially with time, as nuclei in the resultant impurity themselves disintegrate; but it is important to appreciate that a similar compound, prepared from [^{14}C]-carbon dioxide at twice the specific radioactivity, and then diluted with an equal weight of inactive carrier, will produce a different amount of radiochemical impurity as a result of the primary (internal) effect, even though its pattern and degree of labelling appears superficially to be identical with the compound first mentioned.

The amount of radiochemical impurity arising as a result of this effect can be surprisingly large with macromolecules, even when the isotope has a long half-life. For example, a glucose polymer containing 1,000 glucose units, and prepared from [^{14}C]-carbon dioxide having the same isotopic abundance as that used to prepare the sucrose quoted in Table 1, would give rise to 0.28 per cent of radiochemical impurity in one week as a result of this effect.

Conclusion

We have not attempted to give a comprehensive review of this subject. We have rather aimed at

illustrating certain principles and have endeavoured to show that material of very high specific radioactivities can be used, and even stored, under certain conditions, but that a constant awareness of the phenomenon is called for on the part of all users of compounds labelled with radioactive isotopes.

We are indebted to Prof. E. J. Bourne, Dr. J. R. Catch; and Dr. J. S. Glover for helpful discussions.

TRACE ELEMENTS IN AUSTRALITES

By DR. S. R. TAYLOR and MAUREEN SACHS

Department of Geochemistry, University of Cape Town

THE chemical composition of tektites can provide much evidence about their origin. The concentrations of the major elements have been known within close limits for many years, although for some of the constituents present in low amounts, for example, sodium monoxide, the data are of poor quality¹. A few determinations have been made of the elements present in trace quantities. Among the early investigations are those of Preuss^{2,3} and Heide⁴⁻⁶. More recent determinations have been of rubidium^{7,8}, uranium^{9,10}, thorium⁹, lithium, rubidium and cesium¹¹ and of several elements by Cohen¹². None of these data, except for the lithium and rubidium figures given by Cohen¹² (see Taylor¹¹) is very different from terrestrial abundances, and gives any support to theories requiring an extra-terrestrial or extra-solar system origin for these interesting glassy objects. Many of the reported determinations have been carried out as a sideline to other work, or to provide evidence on a particular point, examples being the nickel and chromium determinations of Preuss^{2,3}. No systematic study of one group appears to have been carried out.

In collaboration with R. D. Cherry of the Physics Department of this University, we have been studying the composition of a group of australites kindly provided by the South Australian Museum, Adelaide. The australites are a singularly suitable group for study. They cover a wide area (2×10^6 miles²); occur, with minor exceptions, on the present surface; have been melted less than 10^4 years ago, on the basis of recent potassium-argon ages¹³; show well-preserved evidence of two periods of melting, and cover a wider range in chemical composition than any other group. Evidence is accumulating that they display a regional variation in composition^{11,14}.

Determinations have been completed of trace elements on 14 australites using emission spectrochemical methods of analysis following the methods outlined by Ahrens and Taylor¹⁵. Because of the current interest in the origin of tektites, averages of these results are presented here (Table 1) and briefly discussed in this preliminary account. The analytical techniques for the alkali elements have been described elsewhere¹¹. Copper and gallium were determined using sodium as a variable internal standard, utilizing the similar volatilization behaviour of these elements in the d.c. arc. Anode excitation was employed throughout. The remaining elements, which are

relatively involatile under these conditions, were determined using palladium as an internal standard. All determinations were made in duplicate, and the wave-length range of 2470–9600 Å. was covered, with a total of four exposures using Kodak 103-0 and IN plates. Spectrochemical determinations are particularly liable to systematic bias and it is mandatory to employ standard samples for calibration as close as possible in composition to the samples being analysed. The interlaboratory rock standards, G-1 (granite) and W-1 (diabase)¹⁶, were selected as the most suitable. In general, they bracket the composition of the australites, and differ only in being composed of discrete minerals, in contrast to the glassy tektites. The effect of this difference has not been evaluated, but is believed to be small. Most difficulties due to matrix difference in spectrographic analysis using the d.c. arc arise from the presence of different anions in samples and standards. In fact, the d.c. arc emission spectra of the australites over the entire wave-length range bear a general resemblance to a mixture of these standards, which represent, of course, the two common igneous rock types.

The results are given in Table 1. The average of all the fourteen samples is given, with the extremes of the range in composition. The spread in composition is also expressed as a relative deviation, O (per cent standard deviation), and this should be compared with the analytical precision for individual determinations, given in the same units. It can be seen that the range in composition is greater than the precision of individual determinations, indicating that there are real differences in composition between individual samples¹¹. The detection limits for the spectrochemical methods used are also given. Those elements for which no data are given were sought, but if present, are below the detection limits given. Table 1 also contains figures for the average abundances of the elements in igneous rocks (commonly referred to as the crustal abundance) from Ahrens and Taylor¹⁵, in chondritic meteorites from Goldschmidt¹⁷ (with later additions) and in shales. We wish to direct attention to the general similarity between the abundances of the trace elements in australites, and the average abundance of these elements in the Earth's crust.

Cherry and Taylor¹⁸ suggested that the average major element composition of tektites can be closely matched by a mixture of one part quartz with three parts of the non-volatile constituents of shales. It is

difficult to establish average values for trace elements in shales, but Shaw¹⁹ has considered many of the problems and his data are used, except where indicated. More recent data for strontium²⁰, lead²¹, zirconium²², rubidium and cesium²³, and gallium²⁴ are used to supplement Shaw's results. In general, the trace element data in australites are consistent with derivation from a quartz-shale mixture in which shale is the major component. The relatively higher amount of zirconium in the australites in comparison with shales may well be derived from small quantities of the resistant mineral zircon accompanying the quartz.

In conclusion, the data for chromium, nickel and cobalt given here lend no support to a derivation of tektites from meteorites, or from meteorite collisions with the Earth, or from the Moon. From considerations of the structure and density of the Moon, its overall composition is probably close to that of the chondrites. Material from the lunar surface is probably similar to that in the interior, since there seem to be no selenological processes comparable to geological ones. In addition, the surface material can be expected to be rather rich in nickel and cobalt from meteoritic collisions, and hence rather easily distinguished from terrestrial rocks. Extra-terrestrial theories for the origin of tektites must provide for the duplication of many geological processes to account for the overall pattern of trace element distribution.

Data for the individual samples, together with details of the analytical methods and determinations of the major elements by Dr. H. B. Wuk, will be discussed at length in a subsequent paper.

Acknowledgement is made to the Staff Research Fund of the University of Cape Town and to the Council for Scientific and Industrial Research, Pretoria, for financial assistance. We wish to thank Dr. B. Daily, curator, South Australia Museum, Adelaide, for the australite samples.

A MATHEMATICAL MODEL FOR GAS-LIQUID PARTITION CHROMATOGRAPHY

By DR. J. E. FUNK and PROF. G. HOUGHTON

Chemical Engineering Department, Division of Engineering Research,
University of Pittsburgh, Pennsylvania

THE widespread adoption of gas-liquid partition chromatography for the separation of complex mixtures has led to much speculation with regard to the mechanism of separation. Plate theories of separation have been considered by Martin and Synge¹, Mayer and Tompkins², and Glueckauf³, while continuous or rate theories have been developed by Boyd, Adamson and Myers⁴, Lapidus and Amundson⁵, Glueckauf⁶, Klinkenberg⁷, Tunitiskii⁸, Giddings and Eyring⁹ and by van Deemter, Zuiderweg and Klinkenberg¹⁰. Keulemans¹¹ has summarized the major results obtained by both theories of chromatography. The model discussed in this article essentially includes most of the previous continuous models with the further inclusion of the effects of non-linear solubility and column pressure drop. The use of arbitrary overall mass transfer coefficients has been avoided by separating the resistance to mass transfer into two parts, one due to the gas film and the other due to the liquid film. The describing partial differential equations are:

$$\frac{\partial X}{\partial t} = E \frac{\partial^2 X}{\partial z^2} - \left(u - \frac{2E}{P} \frac{\partial P}{\partial z} \right) \frac{\partial X}{\partial z} - \frac{k_g R T A}{\epsilon} (X - X_1) \quad (1)$$

$$c_1 = K_1 X_1 P + K_2 X_1^2 P^2 \quad (2)$$

$$\frac{\partial c}{\partial t} = D_L \frac{\partial^2 c}{\partial y^2} \quad (3)$$

where $X(z,t)$ is the mole fraction of solute in the gas phase, $X_1(z,t)$ the mole fraction at the gas-liquid interface, $c(y,z,t)$ the concentration of the solute in the stationary liquid phase, $c_1(z,t)$ the concentration at the gas-liquid interface, z the axial distance along the column, y the distance in the liquid film, t is time, $u(z)$ is the average gas velocity through the voids in the packed bed, $P(z)$ the total pressure, T the uniform column temperature, R the gas constant, k_g the 'Whitman' gas-film coefficient¹², E the longitudinal dispersion coefficient (cf. Taylor¹³), ϵ the void fraction, D_L the diffusivity of the solute in the liquid phase, and A is the area of the gas-liquid interface per unit volume of packed bed. The constants K_1 and K_2 are empirical constants in the solubility relationship.

Equation (1) accounts for diffusion in the gas phase, equation (2) represents a nonlinear equilibrium relationship between the gas and liquid phases, and equation (3) is a statement of molecular diffusion in the partitioning liquid. If the liquid film is thin and $c_m(z,t)$ is the concentration at a point midway in the liquid film, then equation (3) can be approximated by the following differential-difference equation:

$$\frac{\partial c_m}{\partial t} = \frac{D_L}{\Delta y^2} (c_1 - c_m) \quad (4)$$

where Δy is half the liquid film thickness.

Numerical Solution of Equations

Equations (1), (2) and (4) have been solved numerically on the IBM 704 digital computer using finite

difference techniques. The inset of Fig. 1 shows the conditions for an initial value problem in which a slug of solute of mole fraction X and length L_1 is suddenly introduced into a carrier gas stream at time $t = 0^+$ by simultaneously opening two gates. The initial conditions for this case are then:

$$X(z,0) = \begin{cases} X, & 0 < z < L_1 \\ 0, & z > L_1 \end{cases} \quad (5)$$

$$\begin{cases} X(z,0) = X_1(z,0) = 0 \\ c(z,0) = c_m(z,0) = 0 \end{cases} \quad L_2 < z < L_3 \quad (6)$$

and the boundary conditions are:

$$\text{gas velocity} = \begin{cases} u, & L_2 < z < L_3 \\ u\epsilon, & z < L_2 \text{ and } z > L_3 \end{cases} \quad (7)$$

$$\text{gas film coefficient} = \begin{cases} k_g, & L_2 < z < L_3 \\ 0, & z < L_2 \text{ and } z > L_3 \end{cases} \quad (8)$$

A study of the parameters that affect gas-liquid chromatography has been made using the computer programme and considering the particular case of the elution of a pure isobutylene slug with argon using dinonyl phthalate as the stationary phase, the column temperature and pressure being 25°C. and 1 atm. throughout. The data were as follows: $L_1 = 5$ cm., $L_3 - L_2 = 50$ cm., $L_2 - L_1 = L - L_3 = 1$ cm., $u = 5$ cm./sec., $A = 131.2$ cm.² per cm.³, $\Delta y = 7.0 \times 10^{-5}$ cm., $K_1 = 1.14 \times 10^{-3}$ gm.-mole per cm.³ atm., $D_L = 6.7 \times 10^{-7}$ cm.² per sec. (cf. Funk¹⁴ and Kesten¹⁵), $k_g = 10^{-5}$ gm.-mole per cm.² sec. atm. Unless otherwise specified, E was taken to be equal to the molecular diffusion coefficient of isobutylene in argon (0.0674 cm.² per sec.) as calculated by the method of Hirschfelder, Bird and Spotz¹⁶.

Below a value of about 10^{-5} gm.-mole per cm.² sec. atm., k_g was found to affect strongly both the retention time and the shape of the elution curve. However, above a value of 10^{-5} , k_g has no effect on the elution curve, indicating that in order to effect good separations, diffusion-rates through the gas film must be high. Fig. 1 clearly demonstrates that the effect of large longitudinal dispersion coefficients is to broaden the elution curve and therefore reduce the resolution without affecting the retention time.

Fig. 1. Effect of longitudinal dispersion coefficient

Fig. 2. Effect of non-linear solubility

Fig. 2 demonstrates that the effect of a nonlinear solubility relationship is to induce considerable skewness and tailing in the elution curve with a consequent displacement of the peak. The direction of tailing is obviously coupled to the nature of the non-linearity.

Analytical Solution of Equations

For the special case of uniform column pressure ($\partial P/\partial z = 0$) and linear solubility ($K_1 = 0$), equations (1), (2) and (4) have been solved analytically by a transform method similar to that of Lapidus and Amundson⁵. The result, however, was found to be unwieldy; in this respect the numerical solution is easier to use and also accounts for the effects of non-linear solubility and pressure drop.

Since the numerical solution shows that longitudinal diffusion has no effect on the retention time but only affects the sharpness of the band, the effect of physical properties on the retention time may be obtained by solving equations (1), (2) and (4) with the assumptions that $E = 0$, $\partial P/\partial z = 0$ and $K_1 = 0$, subject to the initial conditions (6) and the following boundary conditions:

$$X(0, t) = \begin{cases} 0, & 0 < t \\ \frac{0}{X}, & b > t \\ 0, & t > b \end{cases} \quad (9)$$

A solution to this boundary value problem was obtained by Laplace transform methods and reads:

$$\frac{X(L, t)}{X} = \begin{cases} 0, & 0 < t < L/u \\ \int_{t-b}^t \exp\left(-\alpha\left(\tau - \frac{L}{u}\right)\right) \\ \exp\left(-\frac{L}{u}\beta\right) \sqrt{\frac{\alpha\beta L/u}{\tau - \frac{L}{u}}} \\ I_1\left[2\sqrt{\alpha\beta\frac{L}{u}\left(\tau - \frac{L}{u}\right)}\right] d\tau, & t > \frac{L}{u} \end{cases} \quad (10)$$

where

$$\alpha = \frac{D_L}{\Delta y^2} \left[\frac{k_g}{D_L K_1} + k_g \right] \text{ and } \beta = \frac{k_g R T A}{\epsilon} \left[\frac{D_L K_1 / \Delta y}{D_L K_1} + k_g \right] \quad (11)$$

The modified Bessel function of first order, I_1 , can be approximated by an asymptotic expansion if

$2\sqrt{\alpha\beta\frac{L}{u}\left(\tau - \frac{L}{u}\right)} > 10$ so that equation (10) becomes:

$$\frac{X(L, t)}{X} \approx \frac{(\alpha\beta L/u)^{1/4}}{2\sqrt{\pi}} \int_{t - \frac{L}{u} + b}^{t - \frac{L}{u}} \frac{\exp\left(-\left(\sqrt{\alpha}\sqrt{\tau - \frac{L}{u}} - \sqrt{\beta\frac{L}{u}}\right)^2\right)}{\left(\tau - \frac{L}{u}\right)^{3/2}} d\tau, \quad t > \frac{L}{u} \quad (12)$$

Investigation of equation (12) has shown that it is valid for most conditions experienced in gas-liquid chromatography. Since we are only interested in the retention time a further approximation can be made by reducing the duration of the pulse, b , when equation (12) becomes:

$$\frac{X(L, t)}{X} = \frac{b(\alpha\beta L/u)^{1/4}}{2\sqrt{\pi}\left(t - \frac{L}{u}\right)^{3/4}} \exp\left(-\left(\sqrt{\alpha}\sqrt{t - \frac{L}{u}} - \sqrt{\beta\frac{L}{u}}\right)^2\right) \quad (13)$$

The retention time, t_R , is the time at which the above function maximizes, so that:

$$t_R = \frac{L}{u} \left[1 + \frac{K_1 R T A \Delta y F}{\epsilon} \right] \quad (14)$$

where:

$$F = \frac{1}{2} - \frac{3u}{4\beta L} + \frac{1}{2}\sqrt{1 - \frac{3u}{\beta L}} \quad (15)$$

In cases where the liquid film is thin and the column is long, F has a value very close to unity and the volume V of stationary liquid per unit volume of column is $2A\Delta y$ so that:

$$t_R = \frac{L}{u} \left[1 + \frac{K_1 R T V}{2\epsilon} \right] \quad (16)$$

The so-called 'apparent' retention time, t'_R , can be obtained by subtracting the transport time L/u from (16), therefore:

$$t'_R = \frac{L K_1 R T V}{2u\epsilon} \quad (17)$$

Furthermore, if the liquid solution is ideal, K_1 can be calculated by Raoult's law and the vapour pressures of the solute represented by the Clausius-Clapeyron equation, so that:

$$t'_R = \frac{L \rho_m R T V}{2p^0 u \epsilon} = \frac{L \rho_m R T V \exp(\Delta H/RT)}{2B u \epsilon} \quad (18)$$

where p^0 is the vapour pressure of the solute at the column temperature, ρ_m the molal density of the liquid phase, ΔH the latent heat of vaporization of the solute and B is a constant in the Clausius-Clapeyron equation.

Equation (18) predicts that the 'apparent' retention time is proportional to the volume of stationary liquid and the column length, inversely proportional to the vapour pressure of the solute, and independent of the absolute column pressure provided the carrier

gas velocity is constant. The retention time should also be inversely proportional to the carrier gas velocity. Furthermore, according to (18), a plot of $\ln(t'_R/T)$ against $1/T$ will be a straight line. All the above predictions are observed experimentally and discussed by Keulemans¹¹. The detailed comparison of the above theory with experiment will be discussed in further communications.

EFFICIENCY OF SEPARATION IN BUFFERED PAPER CHROMATOGRAPHY OF ORGANIC ELECTROLYTES

By DR. EDWARD SOCZEWIŃSKI

Department of Physical Chemistry, Academy of Medicine, Lublin, Poland

IN chromatographic methods the efficiency of separation of a system in respect to a given binary mixture depends mainly on two parameters: (1) the number of theoretical plates, which determines the spread of a zone; (2) the selectivity, which determines the distance between two zones.

The latter parameter is usually expressed by the separation factor, which may be defined, for example, as the ratio of the distribution coefficients of the two substances to be separated (liquid-liquid extraction), or the ratio of the retention times (gas-liquid partition chromatography), etc. In paper chromatography it is most conveniently expressed as the difference between the R_F values of the substances under study ($\Delta R_F \geq 0$).

In the case of organic electrolytes which in un-ionized form give high R_F values (near 1), improved separation may often be obtained by changing the pH of the water phase¹. Fig. 1a illustrates the variation of the R_F values of a number of substances; in Fig. 1b, curves for ΔR_F as a function of pH are presented, which were obtained by subtracting the ΔR_F values of different pairs of substances at the same pH; for example, curve OA shows the variation of the ΔR_F of components O and A with change of pH of the water phase. It can be seen that often a maximum occurs on $\Delta R_F = f(\text{pH})$ curves; the pH value at which this maximum is obtained may correspond to conditions of optimum efficiency of separation (highest possible differences in R_F values) for the pair of components considered. This optimum pH may be calculated by equating the derivative $d\Delta R_F/d\text{pH}$ to zero; thus, taking into account the formulae derived by Waksmundzki and Soczewiński²:

$$\frac{d\Delta R_F}{d\text{pH}} = \frac{d}{d\text{pH}} \left(\frac{\frac{k'r}{K'_A}}{\frac{k'r}{K'_A} + 10^{\text{pH}}} - \frac{\frac{k''r}{K''_A}}{\frac{k''r}{K''_A} + 10^{\text{pH}}} \right) = 0 \quad (1)$$

where k is partition coefficient of un-ionized substance; r is ratio of volumes of mobile and fixed phases; (kr is partition number of un-ionized substance³); K_A is ionization constant of acid. The indices ' and '' denote first and second component, respectively.

Solution of (1) gives:

$$\text{pH}_{\text{opt}} = \log \frac{\frac{k'r + 1}{K'_A} \sqrt{\frac{k''r}{K''_A}} - \frac{k''r + 1}{K''_A} \sqrt{\frac{k'r}{K'_A}}}{\sqrt{\frac{k'r}{K'_A}} - \sqrt{\frac{k''r}{K''_A}}} \quad (2)$$

The case for $kr \geq 100$. In buffered paper chromatography, the partition numbers kr of the un-ionized substances to be separated often are high, for example, 100 or more; hence the limiting R_F values (when

Fig. 1

Fig. 2

Fig. 3

substances are un-ionized) are greater than 0.99—the substances migrate with the front of the developing solvent. In those cases the shapes of the R_F vs. $f(pH)$ curves are invariable and independent of the parameters K_A and kr , which influence only the positions of the curves. The inflexion point, which lies at the half-height of the curve (R_F about 0.5) and is the centre of axial symmetry of the curve, lies then at the pH value given by the formula:

$$pH_i = pK_A + \log(kr + 1) \approx pK_A + \log kr = \log \frac{kr}{K_A} \quad (3)$$

Thus the horizontal distance between two inflexion points (and owing to almost identical shapes, between whole curves as well, excluding asymptotes) is:

$$D = \log \frac{k'r}{K'_A} - \log \frac{k''r}{K''_A} = \log \frac{K'_A \cdot k'}{K''_A \cdot k''} = \log \beta = \xi \quad (4)$$

or, expressing it in another way, the horizontal distance between a pair of R_F vs. $f(pH)$ curves, when $k'r, k''r \gg 100$, is equal to the logarithm of the separation factor of the substances to be separated, as defined by Golumbic⁴; or it is simply equal to the selectivity ξ (a term introduced by Kemula and Buchowski⁵) of the system with respect to the two

substances, provided that $(H) \ll K_A$. Vice versa, an experimentally determined horizontal distance between two R_F vs. $f(pH)$ curves gives directly $\log \beta$ for the solvent with respect to the two substances. This is illustrated in Fig. 2a, where a number of R_F vs. $f(pH)$ curves is plotted ($kr \gg 100$) with different horizontal distances from the arbitrarily chosen reference curve 0. The relation (2) in this case simplifies considerably (by omitting the 1's from relations 1 and 2), becoming:

$$pH_{opt} = \frac{1}{2} \log \frac{k'r \cdot k''r}{K'_A \cdot K''_A} \quad (5)$$

The resulting error will not exceed 0.01 R_F , which lies within the experimental error of the method. Comparing (5) with (3), it can be easily seen that optimum pH value lies in the centre of the line connecting the pH_i values of a pair of components. In Fig. 2b the ΔR_F of different pairs of components at corresponding pH values are given.

Introducing pH_{opt} into ΔR_F (expression in brackets in formula 1, units omitted) we can calculate the maximum obtainable difference of R_F values between the two components considered:

$$\max \Delta R_F = \frac{\sqrt{\beta} - 1}{\sqrt{\beta} + 1} \quad (6)$$

Fig. 3 presents a plot of function (6), that is, it shows what maximum difference of R_F values may be obtained (at pH_{opt}) with a given separation factor β , as defined by Golumbic⁴. At other pH values the differences of R_F are smaller. Thus formulae 5 and 6 permit the theoretical prediction of the optimum pH value and the maximum resolution, expressed in terms of ΔR_F , from partition numbers and ionization constants of the substances which are being separated.

Since R_F vs. $f(pH)$ curves for bases are mirror reflexions of those of acids (axis of symmetry at $pH = 7$), some of the relations deduced above must be altered if the substance under consideration is a base. Thus:

$$(1) \quad \frac{d\Delta R_F}{dpH} = \frac{d}{dpH} \left(\frac{k'r/K'_B}{\frac{k'r}{K'_B} + 1 + 10^{14-pH}} - \frac{k''r/K''_B}{\frac{k''r}{K''_B} + 1 + 10^{14-pH}} \right) = 0$$

$$(2) \quad pH_{opt. (base)} = 14 - pH_{opt. (acid)}; K_A \text{ replaced by } K_B.$$

$$(3) \quad pH_i = 14 - \log \frac{kr}{K_B}$$

$$(4) \quad \text{unchanged, only } K_A \text{ replaced by } K_B$$

$$(5) \quad pH_{opt.} = 14 - \frac{1}{2} \log \frac{k'r \cdot k''r}{K'_B \cdot K''_B}$$

$$(6) \quad \text{unchanged.}$$

Figs. 1 and 2 can also be adapted to bases by replacing pH values by $14 - pH$ (as shown in Fig. 1).

LETTERS TO THE EDITORS

RADIOPHYSICS

Radio Detection of the Planet Saturn

DETECTION of 3.45-cm. radiation from the planet Saturn has been accomplished with an X-band ruby maser radiometer^{1,2} installed on the 85-ft. (26 m.) diameter, paraboloidal antenna at the University of Michigan's Radio Astronomy Observatory³.

The initial detection on August 25-26, 1960, resulted from seven drift curves, one of which is shown in Fig. 1. The average of the seven drift curves indicates a peak antenna temperature of $0.10 \pm 0.028^\circ \text{K}$. Although the increase at the predicted position of the planet is visible on a single drift curve, the observation was repeated five days later to eliminate any possibility of confusion with radiation from other extra-terrestrial sources. At the time of the second observation, the predicted average change in Saturn's right ascension was 37.3 sec., westward; the measured average change was approximately 36.5 sec., westward. The average of the seven drift curves of the second observation indicates a peak antenna temperature of $0.09 \pm 0.028^\circ \text{K}$. These results are summarized in Fig. 2.

The total of fourteen drift curves, with a 'superimposed epoch' reduction technique, yields a peak antenna temperature of $0.095 \pm 0.02^\circ \text{K}$. This value indicates an equivalent black body disk temperature of $106 \pm 21^\circ \text{K}$., neglecting the effect of radiation from the rings. A correction factor of 2 per

Fig. 1. Drift curve of the planet Saturn obtained with the maser radiometer. $\lambda = 3.45 \text{ cm}$. Peak antenna temperature is about 0.10°K .; integration time, 12 sec.

Fig. 2. Drift curves of planet Saturn, taken five days apart with the maser radiometer; O, August 25-26, ●, August 30-31. Each is the average of seven individual drift curves. Solid lines are gaussian representation, at the expected shift of the planet

cent has been applied for terrestrial atmospheric absorption. This equivalent black body disk temperature is in reasonable agreement with that predicted from optical measurements⁴.

The peak antenna temperature of Saturn is about 350 times less than that measured from the standard source Cassiopeia A with the same system. In 1957, Drake and Ewen⁵, using a 28-ft. antenna and a TWT radiometer at 3.75 cm., reported an antenna temperature for Saturn of 0.04°K . This reported detection was from one observation of 'off-on-off' type. This same paper reports an antenna temperature of 2°K . from Cassiopeia A. Their ratio of 50 could predict an antenna temperature of about 0.7°K . from Saturn, with the 85-ft. antenna of the University of Michigan, as opposed to our measured 0.10°K . The solid angle subtended by the planet during our measurements was the same as during the Drake and Ewen measurement of 1957.

The ruby maser radiometer developed by us is being described fully elsewhere³. Stated briefly, it is a modified Dicke system⁶ with a switching input which is balanced off source on 'cold' sky. The maser preamplifier is a four-level ruby maser operating at 8.72 kMc/s. with push-pull magnetic field of approximately 4,000 gauss. The voltage-gain band-width product is typically 300 Mc/s., with a maser band-width of about 30 Mc/s. System band-width is at present intermediate-frequency limited at 8 Mc/s. The total equivalent system noise temperature is about 100°K ., including antenna spill-over and backlobes. These parameters result in a root mean square fluctuation of about 0.012°K . with a 12-sec. integration time. In Fig. 1 the root mean square fluctuation, taken as 1/4 the peak-to-peak off-source noise, is about 0.015°K . Thus the signal to peak-to-peak noise ratio for Saturn is about 2 to 1, on a single drift curve.

In this observation the modified Dicke system consisted of two identical horns pointed at the antenna surface, but physically separated so as to displace their beams by about 3.5 beam-widths in declination. Thus in all fourteen drift curves the comparison is between two discrete areas of the sky, one of which contains the planet. For small sources such as this, problems of balance and stability of gain are greatly reduced.

GEOPHYSICS

The Outer Radiation Belt and Auroræ

Rees and Reid¹ have found a diurnal variation in the latitude of the hydrogen lines in auroræ observed at College, Alaska. The variation is approximately sinusoidal with latitude minima at local midnight. They explain the phenomena by assuming that auroræ are produced by energetic protons and electrons which are sporadically scattered out of the outer radiation belt and showing that a day-side compression of the geomagnetic field by a continuous solar wind² could produce the latitude shift. The magnitude of the shift during geomagnetically quiet periods requires the solar wind to penetrate to within 4-5 Earth radii from the centre of the Earth. This corresponds to a translational kinetic energy density of about 300-600 keV./cm.² for the wind, which is within the energy-range suggested by other measurements³.

There is additional evidence which seems to corroborate this model. The position of the belt must have a diurnal variation such that the tips are always over the auroral regions at night and the day-side is slightly compressed from the usual dipole shape by the solar wind. The meagre space-probe observations of the belt⁴⁻⁶ listed in Table 1 tend to

Fig. 1. Cross-section of the outer radiation belt in the geomagnetic meridian plane of the solar wind

Fig. 2. Cross-section of the outer radiation belt in the geomagnetic equatorial plane. The labelled points are observed maxima listed in Table 1

support this unsymmetric model. In Table 1, ϕ is geomagnetic latitude; τ is local time; r is the geocentric radial distance in Earth radii; r_s is the radial distance of the dipole projection of r in the geomagnetic equatorial plane; and r_{so} is r_s taking into account the day-side solar wind compression. Figs. 1 and 2 are schematic diagrams of the belt in meridian and geomagnetic equatorial planes. The seasonal variation of the direction of the solar wind and the difference between the geographical and geomagnetic axes have been omitted. In Fig. 2 the labelled points correspond to the space probe measurements listed in Table 1.

Table 1. GEOMAGNETIC CO-ORDINATES OF THE MAXIMUM OF THE OUTER RADIATION BELT

<i>Lunik I</i> (refs. 4, 5)	Jan. 2, 1959	20° N.	0200*	4.2	4.8	4.8
<i>Pioneer IV</i> (ref. 6)	Mar. 8, 1959	0°	0630	3.6	3.6	3.6
<i>Explorer VI</i> (out, refs. 7, 8)	Aug. 9, 1959	7° N.	1820	3.6	3.6	3.6
<i>Lunik II</i> (ref. 5)	Sept. 12, 1959	33° N.	1600*	2.7	3.8	3.2

* The longitudinal logs of these trajectories are unavailable. The numbers were obtained assuming trajectories similar to that of *Pioneer IV*.

The agreement of the space-probe observations with the model may be fortuitous in view of the limited observations. However, all the probes listed in Table 1 passed through the region during geomagnetically quiet periods when *Explorer VI* has shown that the position of the outer belt is relatively stable. The theory could be tested by a single satellite in a highly eccentric orbit with a large rate of longitudinal precession.

Additional characteristics of auroræ might be explained with this model. The compression of the solar wind on the day-side will increase the magnetic field-strength and cause the mirror points of the trapped particles to be shifted nearer the geomagnetic equator. The day-to-night variation in the position of the tip of the belt shown in Fig. 1 was obtained assuming a 75 per cent increase in field-strength. This effect would prevent trapped particles in the belt from reaching auroral altitudes and explain the lack of day-time auroræ during geomagnetically quiet periods. The auroral *H α* profile maximum indicates that a large number of primary auroral protons have energies near 2 keV. (ref. 9), which is the same order of magnitude as the average solar wind proton energy. Parker¹⁰ has shown how instabilities at the interface of the wind and the magnetic field result in Fermi acceleration of the particles (Fig. 1) and could pro-

duce the high-energy component of the auroral proton energy spectrum.

PHYSICS

Observations of the Emission of Light on Dissolution of Irradiated Solids in Certain Liquids

Ahnström and Ehrenstein have observed the emission of light on dissolution of some organic solids in water¹. We have been concerned with measurements of stored radiomimetic energy in solids treated with ionizing radiation. This problem has been approached partly by dissolution in liquids typical for dosimetry by the methods of radiation chemistry and partly by attempts to excite, during dissolution, liquid scintillators². Some results of the latter kind will be summarized here. Most of the experiments were concerned with fine-grained sodium chloride which was given doses up to 200 Mrads of cobalt-60 γ -radiation and 2-MeV. electrons from a Van de Graaff machine.

Emission of light was observed by a photomultiplier (EMI 6255 B) and current recordings³. The solid is poured mechanically, using a manipulator, into a liquid contained in a quartz glass cup (Ekco's design for liquid scintillation counting). The liquid may be water, aqueous solutions, organic solvents or organic solutions.

It was noted that irradiated sodium chloride gave light pulses on dissolution in (aerated) water. The first part of the effect is very fast (rise-time about 0.5 sec.) and thus a fast recorder (Mingograf 230 B from the Elema-Schonander Co.) was selected. Emission of light was observed also for lithium fluoride, potassium iodide, glucose, saccharose and alginic acid. (The shape of the light-pulse of the latter was, however, flatter.)

Dissolution in the liquid scintillator described by Kallman and Furst⁴ containing dioxane, diphenyl-oxazole, naphthalene and water gave less light than water itself, although it responds well to an external caesium-137 source.

It was therefore decided to select solutes, known to be fluorescent to ultra-violet light or X-rays, that are either surface active, that is, exhibiting naturally a rather high concentration within the dissolution zone, or very slightly surface active, that is, having nearly the same concentration in the bulk solution and dissolution zone. Some simple inorganic ions approximate to the last case.

Fig. 1. Record of light emission on dissolution of 10 mgm. fine-grained sodium chloride (*pro analysi*) given a dose of 50 Mrads with 2-MeV. electrons 12 months before experiment (stored at $+4^{\circ}\text{C}.$). Solvent is 4.2×10^{-2} thallium chloride in water. The sodium chloride is dissolved within 1 min. The ordinate is anode current of the photomultiplier tube and well within its linear region. The system is quantitatively calibrated by tritium-water in the same apparatus

Following up these ideas, it was noted that a strong light emission is obtained with diphenyl-oxazole dissolved in water and with a commercial naphthalene sulphonic acid condensed with formaldehyde also in aqueous solution ('Belloid TD', a product of the Geigy Co.). Both systems should be regarded as surface active and the solutes as fluorescent. The total light output (found by measuring the total area of the light output pulse) was now nearly a thousand times greater than in the case of water. In a dark-room, the light flash occurring during dissolution is quite clearly seen. Fig. 1 shows a typical record in which the time-scale is also seen.

Similar experiments were performed with solutions of thallium chloride in water. This system is known to be fluorescent⁵. It seems to be somewhat surface-active. Here also, a large light output was observed—about a thousand times greater than that for water. Also this light flash is readily observed in the dark-room. It was found that the light output has a pronounced maximum at about 0.01 gm./litre thallium chloride.

A comparison with the luminescence of tritium water (~ 100 mc./ml.) containing thallium chloride was made. This solution exhibited a small but easily measurable fluorescence. Assuming that the stored energy acts like radiation and excites the thallium ion electronically, we found that, using 0.01 gm./litre thallium chloride, the energy stored was about 1.5×10^6 ergs/gm. or 3 per cent of the primary absorbed dose. This figure is of the same order as that found by using chloroform as a detector⁶.

It was further observed that irradiated alginic acid gave a light-pulse; but, after storage in humid air (98 per cent relative humidity, $20^{\circ}\text{C}.$) for one day, no light emission was observed.

Irradiated polystyrene samples gave rise to luminescence when dissolved in the liquid scintillator NE 213 (xylene, *POPOP*, from Nuclear Enterprises, Ltd.). Samples treated by electrical a.c.-corona discharges (by Dr. A. Kelén, ASEA Co.) gave similar light pulses, thus yielding a qualitative indication of the equivalence between the action of ionizing radiation and electrical discharges.

Further observations showed that lanthanide ions known to be fluorescent, namely, gadolinium, neodymium, samarium, terbium and europium, did not amplify the water light-pulse for sodium chloride. It is not clear at present why the lanthanide ions do

not give large luminescence effects whereas thallium ions and organic fluorescent solutes do.

These results might be of some significance for health problems which may eventually be encountered in food preservation by irradiation^{1,4}. They show that dry substances store energy but that hydrophilic materials lose this energy on sorption of water. No strict proof of radiation-equivalence is obtained because the average wave-length emitted is around 4000 Å. Nevertheless, the results indicate that the phenomenon of stored energy has to be carefully examined, at least for dry solids, before preservation of food by irradiation is adopted on a large scale. For further details, see ref. 2 and a more complete paper given elsewhere. The work on ionic crystals has some relation to the discussion of stored energy and volcanism⁵.

Aberration of Plane Waves

By 'aberration' is meant the change in the apparent angular position of a source (usually at infinity) due to a change in the velocity of the observer.

In elementary treatments of this phenomenon, the source is considered as a source of particles and the required formula is obtained by applying the rules for addition of velocities. It will be shown here that the result obtained in this simple way is also valid for plane waves with velocity c , but is not valid for plane waves having other velocities. For example, the aberration of sound in Newtonian mechanics is zero, whereas a misapplication of the addition of velocities rule would lead one to think that there should be an aberration of the order of the change in velocity of the observer divided by the velocity of sound.

The fact that there is no classical aberration for sound may be realized by thinking of the following experiment:

A sound-direction finder or sound telescope is made from several small microphones attached to a rigid structure so that they are coplanar; the signals from the microphones are received without appreciable delay by an integrating apparatus which is also part of the rigid structure. When this telescope is activated by the sound from a far distant source, the total signal received is maximum when the signals from the individual microphones are in phase, that is, when the plane of the microphones is parallel to the planes of the oncoming waves. If a change in velocity is now imposed on the telescope, it is clear that the above condition of parallelism will not be destroyed. Hence, no re-orientation of the telescope for maximum signal is necessary, which means that there is no aberration.

Consider two observers O and O' moving with respect to one another, so that O sees O' moving with velocity v in the positive direction of their common x -axis. Let the y and z axes of O be parallel respectively to those of O' . The Lorentz transformations which relate the measurements of these observers are:

$$x = \gamma(x' + vt'); \quad y = y'; \quad z = z'$$

$$t = \gamma\left(t' + \frac{vx'}{c^2}\right), \text{ where } \gamma = 1/\sqrt{1 - v^2/c^2}$$

Suppose O observes the plane wave:

$$\chi = \exp 2\pi i \left(\frac{lx + my + nz}{\lambda} - ft \right)$$

that is, he observes it as moving in the direction (l, m, n) with velocity $f\lambda$.

The manner in which O' observes the same wave can be obtained by substituting for x, y, z and t in terms of x', y', z' , and t' giving:

$$\chi = \exp 2\pi i \left(\frac{l'x' + m'y' + n'z'}{\lambda'} - f't' \right)$$

$$\text{where } \frac{l'}{\lambda'} = \frac{\gamma(l - vf\lambda/c^2)}{\lambda'}$$

$$\frac{m'}{\lambda'} = \frac{m}{\lambda}; \quad \frac{n'}{\lambda'} = \frac{n}{\lambda}$$

$$f' = \gamma\left(f - \frac{lv}{\lambda}\right) = \gamma\left(1 - \frac{lv}{f\lambda}\right)f$$

From these equations one obtains the general aberration formula:

$$l' : m' : n' = \gamma\left(l - \frac{vf\lambda}{c^2}\right) : m : n$$

A common case of aberration is when the oncoming wave is moving roughly at right angles to the relative velocity of the two observers. Let its direction of motion as observed by O be in the direction of the negative y axis, that is: $(l, m, n) = (0, -1, 0)$.

The direction of motion as observed by O' will differ from that of the negative y axis by an angle θ where $\tan \theta = \frac{l'}{m'}$. From the general formula above it is evident that:

$$\tan \theta = \gamma \frac{vf\lambda}{c^2}$$

This formula becomes the usual one $\left[\tan \theta = \frac{v}{c}\right]$ for

the case of astronomical aberration. It also explains why the aberration of waves vanishes in non-relativistic mechanics, that is, as $c \rightarrow \infty$.

Even though the apparent direction of a distant sound source does not depend on the motion of the observer it does, nevertheless, vary with the velocity of the medium relative to the source. This effect may be understood classically as follows:

When a signal is emitted by the source, it progresses as a spherical wave the radius of which grows with the velocity of sound and the centre of which remains fixed in the medium (that is, moves with the wind). The sound telescope of any observer (regardless of his velocity) at a point P must for maximum signal be aimed at the position of the centres of the waves as they pass P . From this it follows that, if s is the unit vector in the direction of the sound telescope at

maximum signal and V the velocity of sound in still air and w the velocity of the wind with respect to the source, the vector $V_s - w$ points in the true direction of the source.

This latter phenomenon should not be treated as aberration because it is not associated with the motion of the observer, and because the direction of the effect is opposite to what one gets from the oversimplified application of the law of addition of velocities referred to at the start of this paper.

I wish to express my thanks to Prof. J. L. Synge for a very stimulating discussion on this topic.

Forces on Charged Particles of a Plasma in a Cavity Resonator

FOLLOWING the methods adopted by Boot *et al.*¹, we have recently undertaken an analysis of the conditions required for the containment of an ionized plasma by electromagnetic waves at high frequency, taking collisions and space-charge forces in the plasma into account. During this work, now being prepared for publication, one of us (H. G.) directed attention to the fact that two types of confining force are present when the plasma interacts with the wave in the presence of large field gradients. One is due to the electric, or induced electric, field acting directly on the electrons, as analysed by Boot *et al.* For this force to be unidirectional, certain relations between amplitude, gradient and frequency of the electric field and electron density must be fulfilled. We call this the Mathieu force, since these relations may be obtained by examining the differential equation which is of the Mathieu type². The other unidirectional force we call the electromagnetic force. This force results from the interaction of the electron current set up by the electron moving in the electric field with the magnetic field component of the electromagnetic wave. This is the force considered by Volkov³.

The nature of the solution of the Mathieu equation may be deduced from an examination of the stability chart (Fig. 1). The operating point (α, q) appropriate to a particular region of the plasma is dependent on the plasma parameters, the generator frequency, and the square of the electric field gradient $(dE_0)/(dx)^2$. For a cylindrical cavity excited in the TM_{010} mode:

$$\alpha = \frac{\omega_p^2}{\omega^2} - \frac{2.75e^2}{m_e^2 c^2} (\omega^2 - \omega_p^2) \times$$

$$\frac{2\omega_p^4 - 3\omega^2\omega_p^2 + \omega^4 + \omega^2\nu^2}{\{\omega^2\nu^2 + (\omega^2 - \omega_p^2)^2\}^{1/2}} \left(\frac{dE_0}{dx} \right)^2 - \left(\frac{\nu}{2\omega} \right)^2$$

$$q = \frac{1.375 e^2}{m_e^2 c^2} \cdot \frac{2\omega_p^4 - 3\omega^2\omega_p^2 + \omega^4 + \omega^2\nu^2}{\{\omega^2\nu^2 + (\omega^2 - \omega_p^2)^2\}^{1/2}} \left(\frac{dE_0}{dx} \right)^2$$

where ω_p is $2\pi \left\{ \frac{ne^2}{\pi m_e} \right\}^{1/2}$; ν is the collision frequency

for momentum transfer between electrons and atoms or ions; $\omega/2\pi$ is the generator frequency; and E_0 is the electric field in the cavity.

Solutions for points (α, q) which lie below a_0 or between a_2 and b_2 , etc., correspond to a unidirectional force on the electrons. Those for

Fig. 1. Stability chart. This diagram is symmetrical about the α -axis

points which lie between a_1 and b_1 , a_3 and b_3 , etc., correspond to exponentially increasing amplitudes of oscillation of the electrons. Although this latter condition is not effective for containment, yet, if collisions between atoms and electrons are appreciable in number, it will result in conversion of the radio-frequency energy into plasma heating.

The Mathieu force and the electromagnetic force both originate from the electric field gradient, although for different reasons, and this makes it difficult to separate them mathematically. However, the role of the Mathieu force may be illustrated by putting $\omega = \omega_p$, when the electromagnetic force disappears.

In general, it may be said that, in the region below a_0 in Fig. 1, the electromagnetic force predominates, while between a_2 and b_2 the Mathieu force predominates; but it should be noted that this is not always true, and the electromagnetic force may oppose confinement for certain values of plasma parameters. It can be shown that concentration of the ionized portion of a partially ionized gas is also feasible. The relevance of this to the experiments of Self and Boot⁴ has not yet been examined in detail, but they would appear to support our conclusions.

In practice, under the most general plasma conditions, it seems unlikely that containment of a fully ionized plasma will be obtained by operating in the (a_2, b_2) region where the Mathieu force predominates, partly due to the large field gradients required, and partly due to the difficulty in obtaining the correct relative values for α and q . Our analysis does show, however, that when the special conditions of plasma resonance as defined by Dutt and Stainsby⁵ are satisfied, and when $\nu \ll \omega_p$, the operating point (α, q) can lie between a_2 and b_2 for moderate input

powers, resulting in a unidirectional Mathieu force on the plasma of appreciable magnitude.

Since completing this analysis we have seen a letter from C. M. Haaland⁶ in which he distinguishes between the Mathieu and electromagnetic forces; but seems not to have noticed the phase-dependence of the latter.

The forces considered above are additional to those due to the pinch effect, considered by N. J. Phillips (private communication) for high-frequency currents, which will be present at the surface of a contained plasma.

It may be of interest to note that our analysis resembles that of Prof. W. K. R. Watson⁷ in his theory of fire-ball formation, except that he apparently omits the space-charge terms and does not consider the electromagnetic force as defined by us. His statement that the charge tends to concentrate at the voltage nodes is supported by the analysis and experiments of Boot *et al.*, Volkov's analysis, the experiments of Glagolev *et al.*⁸, and our own analysis.

Our thanks are due to Mr. J. K. Brown, director of research, for permission to publish this communication.

A New Micrometer Microscope

THE usual method of measuring the dimensions of microscopic objects is to compare them against an eye-piece scale or to use a calibrated filar micrometer eye-piece. Such methods are not capable of great accuracy and are inherently slow and poorly adapted to statistical problems. In order to plot the size distribution of a large number of particles, it is necessary to bring each in turn to the centre of the field and to set it against the scale.

These difficulties can be avoided by means of a double-image system in which two images, sheared by a controlled amount, are viewed. If the separation of the two images of a particle is less than its diameter, they will overlap. If the separation is greater than the diameter, a clear space will be seen between them, and if the separation is equal to the diameter they will just touch. The position of contact can be observed with great precision, and theoretical calculations by J. Dyson (unpublished work) have shown that the accuracy of setting may be considerably better than the resolving power.

Only two double-image micrometer microscopes appear to have been described. McGinn¹ used birefringent elements which introduced some aber-

Fig. 1

ration and gave only a small amount of shear. Timbrell² used a mirror vibrating at 50 c./s. phased with an interrupted light source. The shear was controlled by varying the amplitude of vibration of the mirror. This system requires relatively complicated electrical accessories and cannot readily be used with any type of microscope. A purely optical instrument similar to the Mach-Zehnder interferometer has been constructed in the workshop of this Department by Mr. A. B. Charters and is shown diagrammatically in Fig. 1. P_1 and P_2 are two beam-splitting prisms; M_1 and M_2 are two surface-metallized mirrors. The instrument is constructed as an attachable body that fits just above the objective carrier. M_2 can be rotated through a small angle by means of a differential screw micrometer mechanism, producing a sheared image in one azimuth. Shears equal to the diameter of the entire field of view can be obtained at any power. The direction of shear can be altered by rotating the whole attachment about the optical axis of the microscope; an angular scale is provided. It is thus possible to plot the shape and dimensions of an irregular object in polar coordinates.

A special advantage of this system is its use for plotting statistical size-distribution curves. For this purpose the micrometer is set at a known value. On observing the field of particles, those with diameters greater than this value will give overlapping images, those with diameters less than this value will give two separated images and a few may give images that just touch. The number in each category can easily be determined. The micrometer is then set to another value and the process is repeated. In this way an integrated distribution curve can be obtained without making an actual measurement on a single particle. The instrument can be used with almost any method of microscopy, including phase contrast, and it can be readily applied to living cells, including motile ones.

Many modifications of the basic system are possible. Colour filters can be inserted into one or both paths and are sometimes helpful in distinguishing the sheared from the unsheared image. The three elements, P_1 , P_2 and M_1 , could be incorporated into a single solid block of glass. A modified version in the form of a convenient eye-piece attachment with a different mechanical system, but giving a smaller

total shear, has been designed by Dyson (unpublished work).

METALLURGY

Hydrogen Diffusion in Mild Steels

DESPITE evidence in the literature that hydrogen diffusion in steels does not obey Fick's laws, experimental data continue to be analysed in their terms. A further deviation from these laws is presented here, and its relation to Fick's laws are discussed. An explicit statement of the inapplicability of Fick's laws to hydrogen in steels, at least below 100°, is desirable.

The solution of Fick's laws for the evolution of a diffusing species from a cylinder of radius a , length l in which the species is at uniform concentration at time $t = 0$ and the surface concentration is zero for $t > 0$ is given¹ by:

$$\frac{Q}{Q_0} = \left[4 \sum_{n=1}^{\infty} \frac{1}{\beta_n^2} \exp \left(-\frac{\beta_n^2 D t}{a^2} \right) \right] \left[\frac{8}{\pi^2} \sum_{m=1}^{\infty} \frac{1}{(2m-1)^2} \exp \left(-\frac{(2m-1)^2 \pi^2 D t}{l^2} \right) \right] \quad (1)$$

where Q and Q_0 are the total quantities of the species in the cylinder at times t and zero respectively, β_n is the n th root of the equation $J_0(X) = 0$, and D is the diffusion constant. After a comparatively short time, the first term in the series in the left-hand bracket becomes dominant, and the practice²⁻⁵ is to assume that after $\frac{Q}{Q_0}$ is less than approximately 0.5, the equation followed is:

$$\frac{Q}{Q_0} = \frac{32}{\pi^2 \beta_1^2} \exp \left[-\left(\frac{\beta_1^2}{a^2} + \frac{\pi^2}{l^2} \right) D t \right] \quad (2)$$

If the evolution of hydrogen from a steel cylinder is measured by following the increase in pressure in a constant volume apparatus with time,

$$\frac{Q}{Q_0} = 1 - \frac{p}{p_f} \quad (3)$$

where p and p_f are the pressures at time t and infinity respectively and $p = 0$ at $t = 0$.

Hence after an initial period, from equations (2) and (3):

$$y = \frac{32 p_f}{\pi^2 \beta_1^2} \exp(-Kt) \quad (4)$$

$$\frac{dy}{dt} = -\frac{32 K p_f}{\pi^2 \beta_1^2} \exp(-Kt) \quad (5)$$

where $y = p_f - p$ and $K = \left(\frac{\beta_1^2}{a^2} + \frac{\pi^2}{l^2} \right) D$

Hence if Fick's laws are obeyed, plots of both $\log y$ and $\log \left(\frac{dy}{dt} \right)$ against t should yield, after an initial period, straight lines of slope $-K$ from which D can be obtained.

Fig. 1. Evolution results for $\frac{3}{8}$ -in. diameter cylinder. A, $\log y$ versus t . B, $\log (y - y_1)$ versus t . C, $\log \left(\frac{dy}{dt} \right)$ versus t .

Evolution experiments have been carried out on mild steel cylinders, 4 in. long and with nominal diameters of $\frac{1}{8}$ in., $\frac{1}{4}$ in. and $\frac{3}{8}$ in., which were saturated with hydrogen by immersion in 3 per cent sodium chloride solution saturated with hydrogen sulphide at 25°. Hydrogen evolutions at 65° C. were studied by following changes in pressure in an initially evacuated constant volume gas burette with a mercury manometer until constant pressure was attained. In each case, values of y were calculated, and values of $\frac{dy}{dt}$ were obtained graphically from plots of y versus t .

The results for a $\frac{3}{8}$ -in. diameter cylinder are given as semi-logarithmic plots in Fig. 1. Curve C, displaced vertically for clarity, shows that equation (5) is obeyed to the extent of giving, after an initial period, a line which is straight within experimental error throughout the range in which slopes could be determined graphically. Curve A, however, has curvature over its length and thus shows that equation (4) is not obeyed. This length corresponds to the evolution of 90–95 per cent of the total. Indications so far are that the evolution thereafter is exponential.

It is necessary to show that the results reported here are a measure of the movement of the hydrogen within the steel and not a measure of any surface processes. This can be done by using specimens of different dimensions, and showing that some measured property of the system is a function of the specimen volume, and not of the specimen surface area⁶. The slope of the $\log \left(\frac{dy}{dt} \right)$ versus t plot was found to be a reproducible property and could be characterized by $t_{1/2}$, the time required for $\log \left(\frac{dy}{dt} \right)$ to halve its value. $t_{1/2}$ was determined using cylinders of different radius (a) and Table 1 shows that $t_{1/2}$ varies as a^2 as required.

Table 1

a^2 (in. ²)	0.0622	0.0475	0.0350
$t_{1/2}$ (min.)	155	113	90
$10^3 a^2 / t_{1/2}$	4.0	4.2	3.9

The behaviour of curves *A* and *C* is due to the fact that *y* decays exponentially within experimental error over a limited range; but this decay requires a finite value of *y* at infinite time, that is, the relation $y - y_1 = A \exp(-Bt)$, where y_1 , *A* and *B* are constants, holds during a substantial portion of the evolution. Thus within this range of applicability, $\log \left(\frac{dy}{dt} \right)$ versus *t* is linear, but $\log y$ versus *t* is not. Curve *B* shows that y_1 can be chosen to give a linear plot of $\log (y - y_1)$ versus *t* with the same slope as $\log \left(\frac{dy}{dt} \right)$ versus *t*. Curve *B* shows the deviation from the linear relation at large values of *t*, when *y* is approaching y_1 in value. It follows that curve *C* would show deviations over the same range but with opposite curvature to curve *B*. Direct measurement of this was precluded by the sensitivity of the apparatus used.

This deviation in a plot of $\log \left(\frac{dy}{dt} \right)$ versus *t* has been reported previously for evolutions at higher temperatures², and attributed to the appearance of "residual or slowly-diffusing hydrogen . . . a real component or effect detectable only after the removal of the rapidly diffusing or 'diffusible' hydrogen".

Now for valid diffusion constants to be obtained for a given system, it is essential that all equations derived from Fick's laws be obeyed. There are already important experimental data obtained below 100° which do not obey the appropriate equations derived from Fick's laws^{7,8}. The division of the hydrogen in solution into 'diffusible' and 'residual' fractions in the present case would therefore be based on deviations from an equation which would not be expected to apply.

The present results provide more evidence against the applicability of Fick's laws and additional data to be explained by a comprehensive theory of the behaviour of hydrogen in steels.

Crucible Material for the Growth of Palladium Single Crystals

INVESTIGATIONS in this laboratory of the catalytic activity of palladium indicated that it was desirable, during a particular measurement, to limit the active surface to a single crystallographic plane. For such experiments large single crystals of palladium were required. This resulted in the development of a crystal-growing apparatus (to be described elsewhere) in which the Bridgman¹ method was utilized, and in an investigation of crucible materials suitable for containing molten palladium. The results of this latter work are reported here.

Although metals of the platinum group are quite inert under most conditions, they react with many common substances when molten. The molten platinum

Fig. 1. Palladium ingot—side view

metals will dissolve appreciable quantities of carbon, most of which will be rejected as graphite on slow cooling. Palladium and silicon form the compounds Pd_2Si and PdSi (ref. 2). Palladium and Pd_2Si form a eutectic mixture at 6 per cent silicon, melting at 670° C. Aluminium oxide has been reported to be stable in contact with molten nickel at 1,800° C. in an inert atmosphere³. From the foregoing considerations, pure aluminium oxide was selected as the crucible material (E. M. Wise, International Nickel Co., states in a private communication that he has used aluminium oxide for containing palladium melts). A crucible of morganite (99.7 per cent aluminium oxide), 8 mm. internal diameter, 12 mm. external diameter, 8 cm. long with a rounded, closed end was used.

The crystals were grown by the following technique. Chemically pure-grade palladium moss was compressed in a steel die to small pellets slightly less than 8 mm. in diameter. Approximately 25 gm. of palladium pellets were inserted in the crucible and the crucible placed in the crystal-growing apparatus. This was flushed with argon at room temperature and again at 500° C. The final argon pressure was 3 lb./sq. in. gauge. The palladium was brought to 1,650° C., approximately 95° above its melting point. The crystals were grown at a dropping rate of 3 cm. per hr. No attempt was made to determine the optimum growing-rate.

Crystals 8 mm. × 40 mm. were easily grown under these conditions. A typical ingot is shown in Fig. 1. Except for a 3-mm. region at the top, the entire ingot is a single crystal. The small zone at the top consists of four small crystals of different orientation (Fig. 2). The orientation of the crystal axes of the large crystal with respect to the direction of growth was determined by Laue back-reflexion photographs: a cube edge forms an angle at about 20° with the axis of the ingot.

Liquid palladium does not wet aluminium oxide, and any gas entrapped in the melt tends to adhere to the crucible walls. This gas is difficult to remove. Even when the pressure is reduced to the point where a considerable amount of palladium distils to the cooler parts of the furnace, small surface bubbles occur on the palladium ingot. The surface bubbles which formed at the molten palladium-aluminium oxide interface are clearly visible in Fig. 1.

Aluminium oxide is satisfactory from the point of view of purity. No evidence of reaction between the crucible and molten palladium was found. Spectroscopic analysis indicated 100 p.p.m. of silicon and iron in the crystal—no more than in the starting material.

The results of this investigation show that pure aluminium oxide is satisfactory as a crucible for molten palladium. As no reaction is detectable between the crucible and the melt, the finished crystal can easily be removed from the crucible

Fig. 2. Palladium ingot—top view

because the melt does not wet its container. When aluminium oxide is used as the container in growing palladium crystals, the diameter of the single crystal ingot should exceed the diameter of the crystal desired because of the gas bubbles, which collect at the crystal-container interface.

This investigation has been supported in part by International Nickel Company, Inc., New York.

CHEMISTRY

A Photoionization Detector for Gases and Vapours

SENSITIVE ionization methods for the measurement of low gas and vapour concentration require the ionization of the test gas or vapour under conditions where an inert carrier gas is unionized. Such methods as the ionization of carbon compounds in a hydrogen flame¹ and the reaction between gases and vapours and rare gas metastables² are well established and successful for this purpose. An alternative method is to irradiate the gas mixture with ultra-violet radiation of such a frequency that photoionization of the test gas occurs without any accompanying ionization of an inert carrier gas. In practice an electrical discharge in one of the rare gases or in nitrogen or hydrogen generates photons of energy sufficient for the ionization of almost all polyatomic compounds, but with insufficient energy to ionize simple diatomic gases.

A practical photoionization detector is illustrated in Fig. 1, together with the details of its construction. The gas supply to the discharge which generates the ultra-violet radiation is led through the tube (A);

this tube also serves as a cathode for the discharge, and in use a current of a few m. amp. is maintained between this cathode and the anode (B). The test gas is introduced through the tube (D); this also serves as the collecting electrode for the ions liberated within the chamber enclosed by the second cathode (C). When the discharge is supplied with hydrogen, nitrogen or argon it is necessary to reduce the pressure within the detector to 100 mm. or less; at higher pressures a stable discharge is difficult to maintain. With helium however a stable discharge is possible at atmospheric pressure particularly if the detector is supplied with radiofrequency energy instead of d.c.³. The carrier gas in which the test sample is introduced into the sensing chamber (C) can be almost any gas which is not itself ionized by the radiation from the discharge. Water-saturated air, for example, gives entirely satisfactory results.

Fig. 1. Construction of the detector. A, Inlet for discharge gas and cathode connexion; B, discharge anode; C, measuring chamber anode; D, sample inlet and cathode; E, outlet to water pump. The detector body is of glass, the cathodes of platinum tubing and the anodes are of copper.

The detector illustrated gave a current of approximately 10^{-10} amp. in the absence of ionizable vapour, possibly due to the photoelectric emission of electrons from the surfaces of the measuring chamber (C). In the presence of ionizable vapour, a substantially linear response to vapour concentration was observed up to a signal current of 10^{-7} amp. The efficiency of ionization of propane as a test substance was approximately 0.01 per cent. The response of the detector appeared to be unaffected by gross contamination of its surfaces with dirt or decomposition products and was stable over long periods and on repeated operation. The stability of this device, unlike that of other discharge methods of measuring vapour concentration, is probably due to the fact that the discharge takes place within the hollow cathode (A), which contains only a clean and uncontaminated supply of inert gas. The design shown should not be considered as final, but rather to illustrate the potentialities of this method.

I am indebted to Mr. P. Simmonds for technical assistance.

Absorption Spectra of Copper(II) and Nickel(II) Complexes

It has been demonstrated that there is a definite relation between the basicity of ligands and the stability of the complexes¹⁻³. There are, however, few data in the literature dealing with the relation between these two factors and the absorption spectra; as an example may be mentioned the work of Jones *et al.*⁴.

It is known⁵ that the bands appearing in the absorption spectrum of the electrovalent, normally paramagnetic copper(II) and nickel(II)-complexes, belong to the transition ${}^2E_g \rightarrow {}^2T_{2g}$ and ${}^3A_{2g} \rightarrow {}^3T_{2g}$, ${}^3A_{2g} \rightarrow {}^3T_{1g}(F)$, ${}^3A_{2g} \rightarrow {}^3T_{1g}(P)$ respectively. If the distance between the sub-levels, due to the effect of the electrostatic field of the ligands, increases, then the bands corresponding to these transitions appear shifted to shorter wave-lengths. The polarization of the ligands plays an important part in the formation of the electrostatic field⁶. The short-wave shift observed with the different ligands means increase of the field and simultaneously that of the polarization⁷. The increase of the covalent character of the bonds results also in a shift of similar direction; and further, the intensity of the bands increases with the σ -donor properties of the ligands⁸.

Our experimental results show that the intensity of the bands in the copper(II) complexes increases in the order ammonia-ethylenediamine-1,2 propylenediamine-trimethylenediamine-triethylenetriamine-tetraethylenepentamine (see, for example, ref. 8), whereas in nickel(II) complexes the order is ethylenediamine-ammonia-trimethylenediamine-tetramethylenepentamine-triethylenetriamine. The extinction value of the bands in general increases with the length of the polyamine chain (trimethylenediamine-triethylenetriamine-tetraethylenepentamine) and with the increase of the size of the chelate rings produced (see Table 1).

In copper(II) complexes there are increases not only in the intensity but also in the width and splitting of the bands with the length of the polyamine chain⁹. The change of the extinction value of the bands is not so regular in the case of nickel(II) as in that of copper(II). The $\lambda(\text{water})/\lambda(\text{complex})$ values (that is, the shift in relation to the hydrated ions) compared with the $\log \beta_n$ values, in both the copper(II) and nickel(II) complexes, is in good agreement with a linear relationship (Fig. 1).

In the case of the nickel(II) complexes, the distance between the red band and blue band is considerably changed ($\lambda_{II}-\lambda_{III}$; $\Delta\lambda$). As the stability increases, these bands get nearer to each other, indicating the

Fig. 1. $\log \beta_n$ as a function of $\Delta\lambda$. ●, $\log \beta_4$; ▲, $\log \beta_3$; ○, $\log \beta_2$; □, $\log \beta_1$.

Fig. 2. A plot of $\Delta\lambda$ against λ_{II} (Ni)

approach of the terms ${}^3T_{1g}(F)$ and ${}^3T_{1g}(P)$. The λ_{II} and $\Delta\lambda$ values give a straight line in good agreement (Fig. 2). The $\log \beta_n$ and $\lambda(\text{water})/\lambda(\text{complex})$ values change in almost the same way in the case of both metal ions.

According to the D_q values in the nickel(II) complexes the order may be as follows:

Table 1

A Technique for pyrolysing or vaporizing Samples for Gas Chromatographic Analysis

A TECHNIQUE was recently reported where rapid heating by induction was used to sublime solid inorganic, organic, and metal complexes¹. The fine powdered sublimate was collected on salt plates and infra-red spectra were determined. The results indicated that very small particle size was obtained, as well as very little decomposition even for organic compounds, although the sublimation technique consisted of heating a platinum dish containing the compound from room temperature to white heat in a few seconds.

It occurred to us that the gaseous products of such a sublimation could be introduced into a gas chromatograph and thus separated for further study.

Normally, a fixed-temperature vaporization block is used on gas chromatographs, so that all possible gaseous products are produced instantaneously; however, it is difficult to choose a temperature which is satisfactory for all components. It was hoped that the rapid heating by induction would result in a series of gaseous products being produced as the temperature rose, each vaporizing at an optimum temperature. Since the time required to reach very high temperatures is only a few seconds, each component would be introduced into the vapour state almost instantaneously, and no broadening of peaks should be seen on the chromatograph.

Two advantages were sought for. First, some separation of volatile from less-volatile components should take place by virtue of the slight time required to pass from low to high temperatures; second, the possibility of reducing cracking of materials unstable at high temperatures, since they will volatilize before cracking temperatures are reached. It should also be possible to use this heating technique for vaporizing viscous or high-boiling liquids which cannot be handled by the usual chromatographic techniques. Pyrolysis of polymers can also be done, since extremely high temperatures can be reached. We have concentrated on this latter work at present and would like to report the results. Some results concerning

the other advantages listed were obtained during the work on polymers.

A chromatographic instrument of our own design² was modified so that one loop of a gas valve passed through the induction coil of a Leco model IH-15 furnace. In our instrument it is possible to make this loop part of the column-detector circuit, or place it under vacuum, or make it part of a loop not entering the instrument. Using the first loop it is possible first to pyrolyse a polymer in a vacuum and then introduce the resulting gases into the column-detector circuit. The second loop can be used to pyrolyse while the helium-flow brings the gases through the column-detector circuit. By comparing chromatographs obtained by both techniques, it is possible to see if better separation of components is obtained by rapidly changing the temperature of the sublimation apparatus or by holding it constant. We are assuming here that the technique of pyrolysing into a helium stream gives chromatographs indicative of a changing temperature sublimation apparatus, whereas the technique of introducing the gases into the chromatograph after pyrolysis is complete gives similar results to a constant-temperature sublimation technique. We also cut out the sample loop after a fixed time so that tarry materials cannot enter the column-detector circuit.

It is possible to use a metal sample holder for the polymers and induce heat in it to pyrolyse samples or, alternatively, mix a metal with the polymer and use it to pyrolyse. The latter technique was chosen because it allows a very intimate mixture of metal and polymer to be obtained and therefore homogeneous heating of the sample. Plaskon metal, commonly used for induction heating of steel samples, was used. In addition, in some runs a very fine iron powder was added to obtain very intimate mixtures. A 10/30 ground-glass sample tube was used with the metal sample mixture. The sample was held by glass wool plugs at a fixed geometry.

The chromatographs for a polyurethane polymer pyrolysis is shown in Fig. 1. The upper curve represents the technique of pyrolysing while the helium stream passes over the sample; the lower is that where the pyrolysis is done in a vacuum and then the products are introduced in the helium stream. The point where the furnace is 'fired' gives a mark on the chromatograph, the width of it being a measure of the firing. The first peak is an air peak since some air is always trapped in the solids and released when they are heated. We note a similar pattern is obtained for both techniques, but slight peak displacement is obtained. Sufficient polymers have been run to show this displacement always occurs. For the first technique discussed above, the peaks appear at slightly longer times. It appears better separation of components is also obtained by this first technique as illustrated by the lack of tailing in the long-time peaks of the upper chromatographs.

While more work will be required to establish the best conditions for pyrolysing samples, work to date suggests the first technique has a good deal of promise. A number of variables must be tested, including length of pyrolysis, column packing and temperature, sample geometry and preparation.

A number of interesting experiments suggest themselves for this system. For example, catalytic effects could be studied by introducing catalysts into the sample. Oxidizers could also be introduced to give oxides of the pyrolysis products and these

Fig. 1. Upper curve is the chromatograph of a polyurethane pyrolysate using the technique of introducing the gaseous products into the helium stream during pyrolysis. Lower curve is a similar pyrolysate which was introduced into the helium stream after pyrolysis is complete. Silicon rubber column; 130° C.; chart paper $\frac{1}{4}$ in. per min.; flow-rate 100 c.c. per min. Attenuator readings are given at each peak; 100 being equivalent to full gain setting.

could be studied. Solids, high-boiling and viscous liquids will also be attempted in later work. Kinetic studies on polymer ageing, as well as other systems could also be done.

Harns has reported how the infra-red spectra of pyrolysates can be used for identification². By standardizing our technique a similar identification could be done.

Heterogeneous Catalysis in Hydroformylation

THE original observers of the hydroformylation (Oxo) reaction assumed heterogeneous catalysis. Subsequent workers have attributed, either by specific hypothesis or apparent assumption, both hydroformylation and concurrent hydrogenation (of aldehyde) to homogeneous catalysis by dicobalt octacarbonyl or cobalt hydrocarbonyl. Our recent results, which indicated a heterogeneous character of hydroformylation via cobalt catalysis¹, made it appropriate to wonder if hydrogenation under these conditions were not also in reality heterogeneously catalysed.

The evidence on which arguments for homogeneous catalysis of hydrogenation have been based consists

of observations that sulphur compounds and carbon monoxide, which are known to be poisons for metallic hydrogenation catalysts, do not poison this hydrogenation². It is now proposed that these previous observations can be rationalized in terms of a heterogeneous mechanism if the dynamic equilibrium between metallic cobalt and the cobalt carbonyls is taken into account. It has been pointed out that if cobalt carbonyl is subjected to hydroformylation conditions, a precipitation of cobalt occurs in the reactor, and conversely that cobalt carbonyl is formed if metallic cobalt is subjected to these conditions³. Also, it has been observed that in the presence of organic materials cobalt hydrocarbonyl decomposes to the metal, tetracobalt dodecarbonyl, carbon monoxide and hydrogen rather than to hydrogen and dicobalt octacarbonyl⁴. Applying this concept of the nature of the catalyst to the mechanism of hydrogenation, it becomes readily understandable that surface poisons should not be effective on a cobalt surface in such a dynamic equilibrium system, since the metal is constantly being solubilized and re-deposited. Each such creation of fresh surface allows the aldehyde to compete with the poison for this surface.

It is thus evident that in order to test adequately the heterogeneity of this hydrogenation catalysis, it is necessary to study poisons which affect metallic catalysts in a fashion more fundamental than blocking of surface adsorption. Such poisons are the heavy metals, which enter into the solid catalyst phase and poison its activity for hydrogen reactions by filling the *d*-band holes with the outer electrons of the poison^{5,6}. Experiments in which ions of lead, mercury and bismuth are added in oil-soluble form to a hydroformylation reaction indeed show the anticipated poisoning effect (Table 1).

Table 1. HEAVY METALS AS HYDROGENATION POISONS IN HYDROFORMYLATION MEDIA*

Run No.	Metal ion added	Metal ion (gm. atom/l.)†	Cobalt** (gm. atom/l.)†	Olefin conversion (mole per cent)	Hydrogenation of aldehyde (per cent)
1-5	None	—	0.020	81.8	90.0
6	Lead**	0.0040	0.020	72.1	22.8
17	Mercury**	0.0040	0.020	80.5	70.8
29	Thallium**	0.0040	0.020	78.8	91.0
40	Bismuth**	0.0018	0.020	76.6	43.0

* Conditions were C₃ olefin (mixed isomers), 177° C., 6 hr. reaction time, 3,000 g lb./sq. in. maximum pressure, hydrogen partial pressure varied as the run proceeded from 1,750 to as low as 1,230 g lb./sq. in., depending on the amount of hydrogenation which occurred in the given reaction.

† All metals were added in ionic form. Undoubtedly the bulk of metals do not remain in ionic form, hence concentrations are recorded in gm. atom/l.

Conversely, thallium does not poison the hydrogenation. The oxidation-reduction potentials are such that ions of lead, mercury and bismuth should be reduced to the metallic state when brought into contact with metallic cobalt, whereas the thallium ion should be reduced only to the thallos state.

This experimental demonstration of poisoning of hydrogenation by a recognized class of poisons for metallic catalysts, together with a rationalization of the inactivity of the class of poisons previously studied², indicates that hydrogenation under hydroformylation conditions in reality proceeds via a heterogeneous mechanism in which metallic cobalt is the catalyst.

A full report on this work will be published elsewhere in the near future.

BIOPHYSICS

Thermal and Electrical Properties of Nucleic Acids and Proteins

In 1955, Duchesne and Monfils¹ discovered absorption lines in the frequency-range of 30 Mc./sec. in the sodium salts of deoxyribonucleic acid and nucleoprotein of yeast and of ribonucleic acid of *Escherichia coli*, all in the dry state, when these substances were inserted in the condenser of a super-regenerative oscillator.

It was clear from a detailed study of the whole question² that the main factor determining the occurrence of these lines was the piezoelectric character of the substances, and that they originated from mechanical movements of large groups of particles inside the crystals, or perhaps, in the case of large systems such as those under consideration, inside the molecules themselves. This same remarkable piezoelectric property has recently been observed and analysed by Polonsky, Douzou and Sadron³ using deoxyribonucleic acid of different origins, and it was further discovered by these authors that these substances were ferroelectric, with a Curie point at about 50° C.

In our method^{1,2}, it was shown that the lines are reversibly shifted by temperature and that the displacements called Δ are given by:

$$\Delta = -\frac{1}{\gamma} \frac{d\gamma}{dT} = \alpha \gamma$$

where α is the thermal expansion coefficient (in volume) of the substance, and γ the Gruneisen constant. On applying this formula to the deoxy- and ribo-nucleic acids and nucleoprotein already mentioned, it was found that the Δ 's reached a remarkably low value comparable to that known for quartz and metals, and in fact a hundred times less than those we had measured for ordinary organic compounds.

We have now extended our earlier investigation to include deoxyribonucleic acid of various other kinds, and also some proteins. Further, as a consequence of the low values of the Δ 's, it was possible to infer, according to well-known empirical relationships⁴, that thermal and, perhaps, electrical conductivities ought to be exceedingly high. With the view of verifying

this inference, it was also decided to perform experiments designed to measure the latter properties.

Calf thymus and herring sperm deoxyribonucleic acid on one hand, and rabbit myosin and actomyosin, as well as collagen, on the other hand, were studied in the form of pellets which were prepared at a pressure of 700 kgm./cm.². All the compounds were characterized by a few lines especially in the region 33–35 Mc./sec., so that piezoelectricity seems to be a rather general property not only of the nucleic acids but also of the proteins. The frequency shifts which were measured over a temperature range 77–296° K., led to Δ 's the approximate values of which were respectively 50, 56, 85, 100 and 47×10^{-6} unit. It was found that the absorption lines disappear around 323° K. in the case of the deoxyribonucleic acid. It is to be noted that the accuracy of the measurements was excellent for the herring sperm deoxyribonucleic acid, in which absorption lines were intense and well defined. In all other cases, it was much less satisfactory because the lines were considerably broader. The order of magnitude of the Δ 's is unmodified in the deoxyribonucleic acid series, including those which were measured earlier, and among the proteins the values corresponding to myosins seem to be the highest. In this connexion, the nucleoprotein measured previously was characterized by a Δ definitely greater than in the corresponding deoxyribonucleic acid, and this may result from the influence of the combined protein.

We have also measured the electrical conductivities. As single crystals were not available, we used specimens in the powdered or fibrous state. The samples were generally in the form of a pellet of about 0.3 cm. thick and 1.3 cm. in diameter. The average value of the pressure used to prepare the pellets was 700 kgm./cm.². The specimens were then compressed between brass electrodes. The system was placed in a closed tube filled with dry air and was heated in a thermostat. The electrical resistance was measured using a commercial megohmmeter (B.P.L. RM-175), the applied voltage being 500 V.

In the series of biological substances examined, the variation of the d.c. electrical conductivity with temperature was found to follow the well-known equation for semi-conductors:

$$\sigma = \sigma_0 \exp(-E/2kT) \Omega^{-1} \text{ cm.}^{-1}$$

The activation energies found in the range 273–313° K. were: herring sperm deoxyribonucleic acid 1.80 eV., calf thymus deoxyribonucleic acid 1.80 eV., myosin 1.75 eV., collagen 0.9 eV. Despite the fact that the two samples of deoxyribonucleic acid were not only of different origins but were also in different forms (calf thymus deoxyribonucleic acid was not compressed and was used in its natural fibrous state), they were found to have practically equal E . The constant σ_0 of the herring sperm deoxyribonucleic acid, which was less reproducible than the activation energy, was of the order of magnitude of $10^8 \Omega^{-1} \text{ cm.}^{-1}$. The activation energies must not be considered as very accurate not only because of lack of homogeneity of pellets but also because they are presumed to depend to a certain extent on the quantity of adsorbed water. A sample of herring sperm deoxyribonucleic acid was irradiated with a dose of 10^8 roentgens of gamma-rays of cobalt-60 and no noticeable change was measurable in its semi-conductivity. As the current through the substances reaches a steady value in a few seconds, it seems that the main contribution to the conductivity should be

due to the motion of electrons. This would indeed be in agreement with recent discoveries of Blumenfeld *et al.*⁵, according to which the anomalous magnetic characteristics of nucleic acids found by electron spin resonance are largely connected with the electric anisotropy of the systems.

On the other hand, it seems that the activation energy of myosin is particularly small in comparison with the other proteins, for which values as high as 3.0 eV. are fairly commonly found⁶. The values obtained for σ_0 were about 5×10^3 , which is exceptionally low when compared with that for deoxyribonucleic acid. For collagen, the constant σ_0 may be estimated at $4 \times 10^{-3} \Omega^{-1} \text{ cm.}^{-1}$.

We believe that all these remarkable and very intimately related properties characterizing nucleic acids and nucleoproteins, as well as proteins, must play a large part in the specific biological behaviour of these substances. Indeed, as a result of their well-known peculiar structure, the individual molecules as such may be responsible for most of the properties described here. Experiments now in progress in our laboratory have been devised to test these views.

We thank Dr. G. Hamoir for generously supplying us with samples of myosin.

BIOCHEMISTRY

Identification of the Black Sub-Unit of the Crystallographic Model of Horse Hæmoglobin with the Valyl-Glutaminyl Polypeptide Chain

THE three-dimensional Fourier synthesis of horse hæmoglobin showed four sub-units which were identical in pairs¹. In the model of the molecule, these two kinds of sub-units were painted black and white for distinction, the chief difference being the presence of one reactive sulphhydryl group in each of the two black sub-units and their absence from the white ones.

Chemical and physico-chemical methods have shown that horse globin consists of two types of

Fig. 1. Elution pattern of globin from horse oxyhaemoglobin treated with iodoacetamide. Column, 80 cm. $\times$ 2.2 cm. of 'Amberlite OG-60' type 2 resin. Elution with urea gradient, 2-8 M, pH 1.9

polypeptide chains and each chain is equivalent to one-quarter the molecular weight of hæmoglobin¹⁻⁴. Procedures for the separation of these two types have been devised^{5,6}. One type has the N-terminal sequence valyl-leucyl (*vl*-chains) and the other valyl-glutaminyl (*vg*-chains)^{6,7}. Each of the two types of chain contains one residue of cysteine⁸, but only in one type is the cysteine reactive in the native protein. By determining whether the *vl*- or the *vg*-chain carries the reactive cysteine, we have now been able to correlate the chemical sub-units with those found by X-ray analysis.

Treatment of native hæmoglobin with iodoacetamide should affect cysteine residues on the black sub-units only and give rise, after acid hydrolysis, to S-carboxymethyl cysteine. Riggs and Wells⁹, by a similar method involving N-ethyl maleimide, have located the more reactive sulphhydryls of human hæmoglobin on the β - or valyl-histidyl-chains.

The red cells of fresh oxalated horse blood were washed several times with saline and lysed by dilution with water. After removal of cell debris by centrifugation, a ten-fold excess of iodoacetamide was added. After 1 hr. at room temperature, excess reagent was removed by dialysis against 0.01 M ammonium phosphate, pH 7. The oxyhaemoglobin was crystallized by the addition of ammonium sulphate to 2.0 M. The crystals were filtered off, washed with ammonium sulphate solution, packed wet in a plastic vial and sent across the Atlantic by air mail. On arrival they were put in a refrigerator, but transformation to methaemoglobin had occurred.

The methaemoglobin was reduced in 0.01 M phosphate buffer pH 7 with a five-fold excess of ammonium ferrotartrate and dialysed against water. Globin was precipitated with acid-acetone³ and fractionated by the chromatographic procedure of Wilson and Smith⁶. The preliminary slurrying of globin solution with a portion of resin before addition to the column was omitted. Fig. 1 shows the elution pattern and the fractions selected.

Amino-acid analyses of samples hydrolysed in 5.7 N hydrochloric acid in sealed tubes for 24 hr. at 105°C. were made, using a Beckman-Spinco amino-acid analyser and the procedures of Spackman, Moore and Stein¹⁰. The averages of duplicate analyses (uncorrected for decomposition or incomplete hydrolysis) are listed in Table 1 as μ moles of amino-acid relative to aspartic acid = 14.0.

Table 1. RECOVERIES OF AMINO-ACIDS FROM 24-HR. HYDROLYSATES OF GLOBIN FRACTIONS

Amino-acid	Fraction 1 (μ moles)	Fraction 2 (μ moles)	Fraction 3 (μ moles)
Lysine	11.8	10.8	—
Histidine	10.4	8.8	—
Arginine	3.1	3.9	—
Cysteic acid	0.5	0.1	0.1
S-carboxymethyl cysteine	0	0.6	0.4
Aspartic acid	14.0	14.0	14.0
Threonine	8.7	3.4	4.5
Serine	11.2	5.4	7.0
Glutamic acid	4.8	12.7	12.2
Proline	6.2	5.1	5.5
Glycine	10.6	13.0	12.9
Alanine	16.5	13.8	14.8
Valine	12.8	14.1	14.9
Methionine	1.0	0.9	1.0
Isoleucine	0	0	0.3
Leucine	22.3	19.2	19.5
Tyrosine	2.8	2.9	2.6
Phenylalanine	7.1	7.7	7.7

Except for the presence of cysteic acid, fraction 1 has the composition of 24-hr. hydrolysates of the *vl*-chain, and excepting S-carboxymethyl cysteine and cysteic acid, fraction 2 that of the *vg*-chain. The small amount of isoleucine in fraction 3 is likely to be due to some contaminating protein; otherwise its composition is similar to that of the *vg*-chain.

S-carboxymethyl cysteine was present in fractions 2 and 3 only; none could be detected in the hydrolysate of fraction 1. The valyl-glutaminyl chains must then correspond to the black sub-units of the crystallographic model.

The yield of S-carboxymethyl cysteine, about 0.6 mole/mole polypeptide, is similar to that found earlier⁴. The nature of the oxidation that converted oxyhaemoglobin to methaemoglobin and unreacted cysteine to cysteic acid is being investigated. The occurrence of this oxidation, however, does not invalidate the identification of the black sub-unit with the valyl-glutaminyl polypeptide.

Production of Acid Mucopolysaccharides by Fibroblasts in Cell Cultures

ACID mucopolysaccharides characteristic of connective tissue ground-substance are produced in tissue culture by fibroblasts from a variety of tissues of mesenchymal derivation¹⁻⁴. It would appear that in

the conditions of growth in tissue culture the spectrum of acid mucopolysaccharides typical of a given tissue⁵ is not reproduced. Rather the results suggest that the cultured cells, whatever their tissue of origin, revert to a similar pattern with respect to production of acid mucopolysaccharides in that all secrete into the medium a major fraction of hyaluronic acid and a smaller component of sulphomucopolysaccharide, presumably chondroitin sulphate C^{2,3}. Moreover, the present experiments show that production of acid mucopolysaccharides by 'stock' strains of fibroblasts may continue in tissue culture for long periods of time, up to years.

In order to assess the effects on synthesis of acid mucopolysaccharides of different conditions of growth and nutrition, it was first necessary to devise reliable methods of measuring accurately the amounts of acid mucopolysaccharides produced per cell during any given interval. Only in this way would it be possible to gain information about such issues as the relationship between the rate of cellular proliferation, cell concentration and composition of medium to the formation of a specific product, the acid mucopolysaccharides.

To this end, series of replicate cell cultures were prepared. Cell suspensions derived from trypsinization of the primary outgrowth of osteogenic fibroblasts from explants of stripped new-born rat calvarium were rendered uniform and dispensed in identical aliquots into T-15 culture flasks, each of which then contained approximately the same initial number of cells. Cultures were washed and fed with fresh medium usually every 72 hr. (except as otherwise indicated), each interval constituting a feeding period. 'Used' media withdrawn at each feeding were saved for analysis. The cells grew well on the glass floors and preserved a uniform appearance. They were collected at intervals from groups of flasks for determination by deoxyribonucleic acid (by the diphenylamine method as adapted by Zamenhof⁶ and modified by Burton⁷), and acid mucopolysaccharides (by carbazole determination of uronic acid content from fractions obtained either after exhaustive hyaluronidase digestion, or a protamine precipitation method modified from Bollet⁸). Results were expressed as a ratio of the amount of acid mucopolysaccharides or acid mucopolysaccharides-uronic acid per μ gm. of deoxyribonucleic acid per flask, the specific production, and as a rate, the specific production per hour. The mean amount of deoxyribonucleic acid present over a given period was calculated whenever possible as a more representative value than either the initial or terminal deoxyribonucleic acid values for that period.

Production of acid mucopolysaccharides on growth media. At moderate rates of growth in a 'biological' medium consisting of 20 per cent human cord serum, 50 per cent beef amniotic fluid, and 30 per cent Earle's balanced saline solution, the acid mucopolysaccharides uronic acid: deoxyribonucleic acid ratio ranged from 1.6 to 4.0 (mean = 2.75 ± 0.18). This average corresponds to approximately 47×10^{-13} gm. acid mucopolysaccharides per average cell, if it is assumed that each cell is equivalent to a diploid rat cell containing 6.8×10^{-12} gm. of deoxyribonucleic acid (Leslie, 1955), and that its uronic acid content constitutes 40 per cent of the acid mucopolysaccharide molecule.

Analysis of specific production and its rate by intervals revealed that within 20 hr. after the first feeding following set-up (that is, Period II of Table 1) a specific production of 1.83μ gm. acid mucopoly-

saccharides-uronic acid/ $\mu\text{gm.}$ mean deoxyribonucleic acid had occurred, while the deoxyribonucleic acid had increased 60 per cent, its maximal rate of increment. The amount of acid mucopolysaccharides released in this time was 47 per cent of the total produced over the whole (79 hr.) feeding period. In the next 59 hr. of this period, deoxyribonucleic acid increased an additional 41 per cent, during which time specific production was $1.4 \mu\text{gm.}$ acid mucopolysaccharides-uronic acid/ $\mu\text{gm.}$ mean deoxyribonucleic acid and the production-rate was 0.023, a decrease of 75 per cent. The acid mucopolysaccharides-uronic acid/final deoxyribonucleic acid ratio for the whole 79-hr. feeding period was 2.24; specific production for the whole period on the basis of the mean deoxyribonucleic value was 3.1. Within period III, that is, the subsequent period following the second feeding, the same relationships obtained, so that in the segment of this period during which the rate of increase of deoxyribonucleic acid was greatest, that is, the first 34 hr., production-rate was also greatest. Such results suggested a direct, rather than a reciprocal, overall relation between rate of cell population increase and synthesis of acid mucopolysaccharides in a relatively rich medium promoting moderate growth. With still higher rates of growth (obtained on a low-serum growth-stimulating medium consisting of 5 per cent cord serum, 75 per cent Eagle's medium and 20 per cent whole egg ultrafiltrate) the increment of acid mucopolysaccharides produced did not keep pace with the increase in deoxyribonucleic acid; specific production was generally not as high as that measured during comparable periods of moderate growth on high serum media with amniotic fluid instead of whole egg ultrafiltrate.

Conversely, when cultures nourished on these growth media became 'crowded', that is, as the cells of the monolayer became contiguous, the rate of cell proliferation declined. This reduced growth was accompanied by a decreased specific production of acid mucopolysaccharides.

Production of acid mucopolysaccharides on maintenance media. Maintenance media consisting of 2 per cent dialysed cord serum, Earle's balanced saline and variable proportions of Eagle's medium supported seemingly healthy cell life, but with little or no growth, for six or more feeding intervals. Increased proliferation could be effected in such media by augmenting the proportion of Eagle's medium. Acid mucopolysaccharides continued to be produced by cells in maintenance media, in some instances attaining

a specific production ratio as high as 1.0; but in no case was specific production greater than 1.0; more usually it was less (Fig. 1). Addition of glucose, known to be a substrate for synthesis of acid mucopolysaccharides, in concentrations of 0.04–0.3 per cent in maintenance medium has no appreciable effect on specific production.

Distribution and kind of acid mucopolysaccharides produced in cell culture. A fraction of the total amount of acid mucopolysaccharides synthesized in any culture remained bound to the cells after washing with either warm or cold saline. This cell-bound acid mucopolysaccharide usually amounted to about 10 per cent of that secreted into the medium. However, in conditions of crowding, the proportion of cell-bound acid mucopolysaccharides to the total increased markedly and reached high levels in extremely dense 'stock' cultures. In some series of analyses of very crowded non-growing stock cultures, specific production tended to be stabilized at about 0.6.

The acid mucopolysaccharides produced by both stock strains of rat osteogenic fibroblasts and recently isolated cell lines was predominantly non-sulphated, and had the properties of hyaluronic acid. After addition of sulphate labelled with sulphur-35 to the

Fig. 1. Growth and production of soluble acid mucopolysaccharides over successive feeding periods by cell cultures of recently isolated rat fibroblasts. Cultures were grouped at random and transferred to either growth or maintenance medium at the end of period II. Differences in growth and total and specific production of acid mucopolysaccharides (see text) 96 hr. later are graphed. Slight growth and production of acid mucopolysaccharides continued on maintenance medium.

AMPS, acid mucopolysaccharides; UA, uronic acid; DNA, deoxyribonucleic acid.

medium, sulphate was fixed in not more than 5–10 per cent of the acid mucopolysaccharides secreted by the fibroblasts. Chemical fractionation and analyses of the acid mucopolysaccharides produced by cultured fibroblasts are in progress.

These investigations were aided by grants from the United States Public Health Services (A 817) and from the American Otological Society. We are indebted to Drs. Karl Meyer, F. Linker and C. Ragan for their interest and help.

Since submission of this paper, additional data have been published in *Ann. N.Y. Acad. Sci.*, 86, 878 (1960).

A Rapid Dialyser for Small Samples

WHILE purifying enzymes, it became necessary to dialyse small amounts of a suspension with maximum efficiency, without allowing the precipitate to settle. This led to the design of a rapid dialyser of simple construction, which we call a 'flat dialyser'.

The dialysis cell consists of a frame (Fig. 1) cut from a 1-mm. thick 'Plexiglas' sheet. This is slipped into previously moistened Visking seamless cellulose tubing (2½ in. wide: for sizes of tubing mentioned later only the inflated diameter will be given), inside which it fits snugly, leaving about 5 cm. of tubing on each side. One of the ends of the tubing is then wound on a 'Plexiglas' strip (0.3 × 0.7 × 7 cm.) and fastened on to the frame with a wide rubber band *F* (Fig. 2). If the length of the tubing has been correctly chosen, in the last turn some tension will be applied to the membrane, thus stretching it over the frame. The solution to be dialysed (up to 1.5 ml.) is then introduced from the open end with a Pasteur pipette, and most of the excess air is driven out by pressing the cellulose tubing between the fingers. The open side of the cell is then closed in the same way as the other

Fig. 1

Fig. 2

one. The assembled dialysis cell is inserted into a rubber band *R*, which is tied on one side to a glass rod *G*, supported by a clamp, and on the other side to a weight *W* and to a length of string *S*. The other end of *S* is made into a loop and hooked from the glass crank *C*, which is driven by a motor at about 60 r.p.m., thus imparting an up-and-down motion to the dialysis cell. The air bubbles entrapped, together with the liquid in the triangular spaces *T*, help to stir the solution. The whole apparatus is placed in a 1,000-ml. beaker, containing at least 600 ml. of liquid. When the dialysis is completed, one side of the cell is unrolled, the cell is held in an oblique position and the liquid is sucked out with a Pasteur pipette.

This arrangement was compared with other methods by dialysing 1 ml. samples of 0.1 *M* sucrose at 1° C. against 800 ml. of water for different times, and analysing the solution that remained in the bag. The results, corrected for changes of volume during dialysis, are shown in Fig. 3. Most of the points are average values of duplicate, and in some cases triplicate, experiments. Under condition *A*, 8/32 in. cellulose tubing containing the sample was tied on both ends, leaving a small bubble of air inside and placed in a beaker provided with a magnetic stirrer. Condition *B* was similar but the diameter of the tubing was larger (18/32 in.) and about three-fourths of the inner space were occupied by air under a slight pressure. When the magnetic stirrer was set at a high speed, the bag revolved on its vertical axis so rapidly that the liquid rose on to the sides, thus increasing the useful surface for diffusion and probably the internal agitation. In order to eliminate possible discrepancies arising from variations in permeability of the different sizes of cellulose tubing used¹, condition *A* was repeated with the 18/32 in. tubing. This arrangement is called condition *C*. Condition *D* refers to an 8/32 in.

Fig. 3. Time-course of dialysis with different methods

tubing, containing an air bubble and a glass bead and placed in a rocking dialyser. Finally, condition *E* was the arrangement first proposed by Seegers^{1,2}, where a glass tube closed at both ends was placed in the cellulose bag, thus confining the solution to be dialysed to a thin layer in the annular space formed. In this case also the bag was placed in a rocking dialyser.

It can be seen in Fig. 3 that conditions *A*, *C* and *D*, with a membrane surface about a quarter that of the flat dialyser, gave similar results, while condition *B* was appreciably superior. The flat dialyser was the most efficient, followed by condition *E*. Since in the last two cases the membrane surface in contact with the inner liquid was about the same, the difference was probably due to the internal stirring obtained in the flat dialyser. It should be noted that condition *E* was unsuitable for our particular purpose, because the precipitate sedimented during the run.

In another experiment 2 *M* ammonium sulphate was used. After 30 and 60 min. dialysis under condition *A* the amount of salt remaining in the bag was 40 and 13 per cent respectively. The corresponding values for the flat dialyser were 3.8 and 0.6 per cent.

We are indebted to our colleagues of the Instituto de Investigaciones Bioquímicas 'Fundación Campomar' for many useful discussions. This work was supported in part by a research grant (No. G-3442) from the National Institutes of Health, U.S. Public Health Service and by the Rockefeller Foundation.

Phenazine Methosulphate as a Mediator in the Oxidation of Pyruvate by Pyruvate Decarboxylase from Brewer's Yeast

PURIFIED pyruvate decarboxylase from brewer's yeast¹ is not only capable of decarboxylating pyruvate to acetaldehyde and carbon dioxide², but can also catalyse the oxidation of pyruvate to acetate with 2,6-dichlorophenolindophenol as artificial hydrogen acceptor³. Ferrieyanide cannot act as a hydrogen acceptor with pyruvate decarboxylase irrespective of whether the enzyme is prepared from yeast³ or wheat germ⁴.

We now find phenazine methosulphate to be an excellent electron carrier for the oxidation of pyruvate by pyruvate decarboxylase from brewer's yeast. Although phenazine methosulphate is not reduced to any measurable extent as no extinction changes were observed at 360 and 405 m μ , it accelerated the reduction of 2,6-dichlorophenolindophenol by some 120 per cent and made possible the otherwise scarcely measurable reduction of ferrieyanide (Fig. 1).

The reaction-rate is not dependent on the concentration of ferrieyanide. At pH 7.4 there is significant non-enzymatic reduction of 2,6-dichlorophenolindophenol and ferrieyanide respectively, but under the conditions of our experiments (pH 6.0) the non-enzymatic reaction is negligible. That phenazine methosulphate works only as a carrier, and is not itself reduced to a measurable extent could be related to its negative redox potential⁵.

Fig. 1. Acceleration of reduction of DCP and potassium ferrieyanide by addition of varying concentrations of phenazine methosulphate. In cuvette ($d = 1$ cm.) 1.0 ml. *M*/20 pyruvate, 1.8 ml. *M*/6 citrate/sodium hydroxide buffer pH 6.0, 0.01 ml. purified yeast carboxylase¹ (protein content as above), and DCP or potassium ferrieyanide as detailed above; total volume 3.0 ml. Upper curve, 40 μ m. DCP/ml.; 80 μ m. enzyme protein/ml.; lower curve, *M*/300 potassium ferrieyanide; 300 μ m. protein/ml. DCP = 2,6-dichlorophenolindophenol

In recent experiments with pyruvate labelled with carbon-14, compounds of pyruvate and acetaldehyde with thiamine pyrophosphate (activated pyruvate and activated acetaldehyde) were found to be intermediates of pyruvate decarboxylation⁶. Considering these findings and other previous experiments on the oxidation of pyruvate with 2,6-dichlorophenolindophenol³ a possible reaction sequence which would account for the effects illustrated in Fig. 1 would be: pyruvate $\rightarrow$ α -lactyl-thiamine pyrophosphate (activated pyruvate) $\rightarrow$ α -hydroxy-ethyl-thiamine pyrophosphate (activated acetaldehyde) $\rightarrow$ α -oxoethyl-thiamine pyrophosphate (acetyl-thiamine pyrophosphate) $\rightarrow$ acetate, the penultimate step being brought about by phenazine methosulphate and 2,6-dichlorophenolindophenol or ferri cyanide.

Elution of Alkaloids from Citrate-buffered Paper Chromatograms

ONE of the most satisfactory methods of paper chromatography of alkaloids is the butanol-citrate system introduced by Curry and Powell¹. It suffers, however, from the disadvantage that if one attempts to elute the alkaloid with chloroform for subsequent confirmatory tests, a certain amount of citrate is also extracted. This interferes with certain important colour tests, as the yellow colour which it gives with concentrated sulphuric acid modifies any colour given by the alkaloid. For example, morphine with the Marquis reagent gives a muddy brown instead of a clear violet.

This drawback can be overcome by converting the citrate to the barium salt, which is much less soluble in organic solvents. The chromatogram spot is cut out and, if the paper has been sprayed with iodoplatinate or iodobismuthate, decolorized with a drop of 10 per cent sodium sulphite solution. It is then dried, treated with a drop of a 10 per cent solution of barium chloride, re-dried and the free base liberated by the addition of a drop of concentrated ammonium hydroxide solution. After again drying, the alkaloid is eluted with chloroform^{2,3}, and its identity confirmed by suitable colour and micro-crystal tests⁴.

Production of D-Araboascorbic Acid by *Penicillium*

WE have found that some species of *Penicillium* produce D-araboascorbic acid. Rarely has this acid been found in biological material or products. Isherwood *et al.*¹ have found it in cross seedlings in D-altrono- γ -lactone solution and in the urine of a rat injected with D-mannono- γ -lactone.

P. decumbens, *P. chrysogenum*, *P. chrysogenum* mut. *fulvescens* Takashima Arima and Abe, *P. notatum*, *P. meleagrinum* and *P. cyaneofulvum* produced D-araboascorbic acid from sucrose.

The following medium was used (per cent): glucose or sucrose, 2; sodium nitrate, 0.1; ammonium sulphate, 0.1; urea, 0.1; potassium dihydrogen phosphate, 0.25; crystalline magnesium sulphate, 0.1; crystalline manganese sulphate (trace); and crystalline zinc sulphate (trace); pH 5.2. The *Penicillium* was incubated for five or seven days at 25–27° C. The broth showed strong reducing activity to 2,6-dichlorophenol indophenol. The contents in the broth were up to 3 mgm. per ml. After the broth was cleared of impurities, the supernatant was run through the anion resin 'IR-4B' column². 1 N hydrochloric acid solution was used in elution. The effluent was evaporated *in vacuo* to a syrup at 25–30° C. under an atmosphere of carbon dioxide. After the syrup was dried in a vacuum desiccator for three or five days, white crystals were obtained. These were recrystallized from methanol dioxane mixture. The 2,4-dinitrophenyl hydrazone was prepared from the resin effluent³. The chemical properties of the free crystal and the osazone are shown in Table 1 and their infra-red absorption spectra in Figs. 1 and 2.

D-Araboascorbic acid was produced from D-glucose, D-gluconate and sucrose only; but not from other carbon sources, for example, glycerin, 2-keto-gluconate, glucuronate and galacturonate. These observations make it seem possible that the conversion of carbon source into D-araboascorbic acid occurs without rupture and inversion of the carbon chain. The stereochemical relation between glucose and D-araboascorbic acid was studied by means of isotopes. The replacement culture by the intact cells

Fig. 1. Infra-red absorption spectra of free crystal

Fig. 2. Infra-red absorption spectra of 2,4-dinitrophenyl hydrazones

of *P. notatum* was carried out with D-glucose-1-¹⁴C as a tracer. The D-araboascorbic acid was isolated by paper chromatography from the broth and crystallized. In order to determine the distribution of the isotopic carbon, the crystals were decarboxylated in 8 N sulphuric acid at 100° C. for 3 hr., and the residual, furfural, was burned and the radioactivities measured in barium carbonate³. It was found that D-glucose-1-¹⁴C was converted to D-araboascorbic acid with 80 per cent of its activity in the carbon 1.

RADIOBIOLOGY

Prevention of the Lethal Effect of the Decay of Incorporated Phosphorus-32 by Growth at 45°

In recent years there has been a growing conviction that understanding the effects of radiation on bacterial cells requires distinguishing between the primary radiation targets on one hand and the metabolic events which ensue, on the other¹. Even if the primary target is, or includes, deoxyribonucleic acid, as is the case for irradiation with ultra-violet light of wave-length 2537 Å. and for X-irradiation, the probability of survival can be increased by such post-irradiation treatments as exposure to visible light², incubation at elevated temperature³, antibiotic-induced inhibition of protein synthesis⁴, etc.

Inactivation of bacteria by the decay of incorporated phosphorus-32 represents another instance where the targets include deoxyribonucleic acid⁴. It is therefore of interest to report that here too the lethal chain of events may be modified after primary damage has presumably occurred. Cells of *Escherichia coli* strain *B* containing phosphorus-32 which fail to form colonies if incubated at the usual temperature of 37°, will do so if incubated at 45° instead.

Carrier-free phosphorus-32 in the form of orthophosphate was obtained from E. R. Squibb and Sons, New Brunswick, New Jersey. The techniques employed to incorporate the isotope and to measure survival have been described by Fuerst and Stent⁵. The only deviation from their procedure was to freeze and store the radioactive and control aliquots at -78° instead of -196° . After thawing, cells were spread on the surface of two sets of nutrient broth agar plates. One set was incubated at 37° and the other at 45° . The numbers of colonies appearing were counted after 24 hr.

Non-radioactive control cells tested immediately after growth and after various periods of storage in the cold did not show a difference in colony count between plates incubated at 45° and at 37°. Cells containing phosphorus-32 also showed no difference when plated immediately after the incorporation of the isotope. The effect of 45° incubation on *B* cells tested during the course of decay is illustrated in Fig. 1. A long plateau in the curve for 45° incubation was observed in repeated experiments and a short plateau was observed occasionally in the curve for 37° incubation.

It has been shown that the cellular processes which determine the lethal and genetic effects of ionizing and ultra-violet radiation are completed in a time corresponding to less than one division⁸. By means of temperature-switch experiments⁹, it was found that this generalization also applies to the lethal effect of decay of phosphorus-32. As shown in Fig. 2, when thawed and plated cells are incubated first at 37°, recovery decreases rapidly if transfer to 45° is made at later than $\frac{1}{2}$ hr. Conversely, if the first incubation is at 45°, recovery begins immediately and 50 per cent of potentially reactivable cells can be rescued by 1 hr.

Fuerst and Stent⁵ found that radioactive cells of *E. coli* strain 157, a thymine-less mutant, exhibited an increased lag before division at 37°. Control cells started to divide almost immediately, but cells containing phosphorus-32 did not begin until 14-2 hr.

Fig. 1. Survival of phosphorus-32-containing *E. coli* B as measured by incubation at 37° and at 45°. Specific activity, 10 mc. phosphorus-32 per mgm. total phosphorus

Fig. 2. Effect of changing incubation temperature at various times after plating. O, First temperature = 37°; X, first temperature = 45°. The data were obtained when 17 per cent of the phosphorus-32 atoms had decayed. At this time, no recovery corresponded to 0.5 per cent survival and maximum recovery to 12 per cent survival

(depending on the amount of phosphorus-32 decay that had occurred). By re-spreading experiments⁷, a lag of $\frac{1}{2}$ -hr. was found for control *B* cells at 45° and 1 hr. for radioactive *B* cells at 45° (1 per cent survival at 37°). A point of interest is that the growth of the cells containing phosphorus-32 at 45° was synchronized, in agreement with previous observations at 37°⁸.

Reduction of the lethal effect of phosphorus-32 incorporated into strain *B* could not be obtained by other treatments which are effective after irradiation with ultra-violet. Photo-reactivation was attempted by diluting thawed cells into physiological saline and exposing to light of wave-length 3650 Å. (ref. 8) for 1 hr. before plating. No increase in survival was obtained. Substitution of M9-agar⁹ for nutrient broth agar also had no effect, that is, the colony counts on the two media were identical after 37° incubation and also after 45° incubation.

The effects of phosphorus-32 decay on the bacterial cell resemble the effects of X-rays and ultra-violet radiation in the following particulars: prolongation of the lag¹⁰, 'reactivability' and the existence of a sensitive period during which 'reactivation' can be obtained. Although the initial physical events are quite different for these three agents, it would appear that the biological events which they trigger must have some features in common.

I wish to thank Miss Eva Simson for technical assistance.

Effects of X-irradiation on Papillary Muscle of the Cat

A NUMBER of investigations have been carried out on the influence of X-rays on the electrophysiological and mechanical properties of striated muscle¹⁻⁵. Most of these experiments have been performed on frog's sartorius muscle, and have revealed the fact that striated muscle generally shows a high X-ray insensitivity. Only minor changes of the membrane resting potential could be recorded during the first few hours following a heavy X-irradiation (80-250 kr.). Similar results were obtained by us (Schliep, H. J., Kraupp, O. and Pillat, B., unpublished results). A 1-mV. decrease of resting potential was produced by an average of 160 kr. (50 kV. 25 m.amp.). Further investigations on the same preparation showed that doses between 300 and 500 kr. practically did not influence intracellular action potentials recorded at

Fig. 1. Ordinate: Average percentage changes of membrane resting potential, action potential, rate of rise, 20, 50, and 90 per cent repolarization time and mechanical tension compared with the average control values of all experiments performed (100 per cent). Abscissa, Time in min. post-irradiation. Upper row, 200-250 kr./10 min.; middle row, 300-375 kr./15 min.; lower row, 400-500 kr./20 min. Black bars indicate exposure to irradiation.

5-min. intervals before, during and after irradiation (Kraupp, O. and Pillat, B., unpublished results).

However, no electrophysiological work concerning the effect of X-irradiation on heart muscle fibres has so far been reported. For that purpose membrane resting and action potentials were recorded with the intracellular micro-electrode technique from papillary muscles of cats. The method has been described in detail elsewhere⁶. An unfiltered X-ray source (50 kV., 25 m.amp.) was used at dose-rates between 20 and 25 kr./min. at an approximate distance of 10 cm. from the preparation.

In this way, three groups of experiments were carried out. Keeping the dose-rate constant (20-25 kr./min.), the duration of X-irradiation was varied. In four experiments the exposure to X-rays lasted 10 min., in six 15 min. and in two further experiments, 20 min.

In all these experiments measurements of membrane resting potential, action potential, rate of rise of the action potential, 20, 50 and 90 per cent repolarization time and of the mechanical tension were performed at 5-min. intervals for at least 1 hr. before and after X-irradiation.

To give a clear demonstration of our results the experiments of each group irradiated were combined. Changes of each parameter were expressed as percentages of the mean control values. As can be seen from Fig. 1, X-ray doses between 200 and 250 kr. had no significant influence on any of the parameters recorded. If the total X-ray dose was increased to 300-375 kr. definite changes of all parameters could be seen. These changes consisted in a decrease of the membrane resting and action potential, in a reduced rate of rise, and in a shortening of the 20, 50 and 90 per cent repolarization time. At the same time the muscular tension was diminished. At total radiation doses between 400 and 500 kr., the changes of all recorded parameters were even more pronounced. Two facts of interest were observed at total X-ray doses above 300 kr.: (1) The observed effects were most pronounced immediately after X-irradiation. (2) All irradiation-induced effects were reversible, at

least to some extent, within 1 hr. Almost complete restitution of the normal repolarization time was found (Pillat, B., Kraupp, O., and Heistracher, P., unpublished results).

All the changes described are illustrated by a sequence of action potentials recorded before and following X-irradiation in a typical experiment (Fig. 2).

The above-described radiation-effects on heart muscle fibres resemble to some extent those obtained with 2,4-dinitrophenol or iodoacetate after incubation of rat's atrium in a solution of these substances⁷. Similarities between the effects of X-irradiation and of 2,4-dinitrophenol on striated muscle fibres have been reported by Woodbury⁸. This points to the possibility that reversible

inhibition of some essential metabolic steps might be involved in the mechanism underlying the

Fig. 2. Action potentials recorded in a typical experiment (total irradiation: 345 kr./15 min.) before, immediately after, and about 1 hr. after irradiation. Left column: slow sweep record. Right column: fast sweep record. Ordinate 10 squares represent 100 mV.

observed radiation effects as reported in this communication. The question arises whether the changes are due to a direct influence of radiation on the cell membrane or to a radiation-produced chemical substance; such a primary radiochemical step could be the formation of hydrogen peroxide.

This investigation was supported by funds from the International Atomic Energy Agency.

Sensitization of *Escherichia coli* to Gamma-Radiation by N-Ethylmaleimide

WITH the exception of oxygen and nitric oxide, chemical agents which enhance the effect of radiation on bacteria have received little attention. In the experiments to be described, N-ethylmaleimide is shown to be a sensitizing agent for *Escherichia coli* strain B/r. A sensitizing agent is taken here to be one which enhances radiation-damage when added before or during irradiation but not after irradiation.

N-ethylmaleimide was obtained from the Aldrich Chemical Co.; it was dissolved in sterile 0.067 M phosphate buffer to make a 0.01 M stock solution which was kept at 3° C. diluted as required. Sterilization of this solution was not found to be necessary. 20–24 hr. cultures on nutrient agar slopes were washed off with 10 ml. of 0.067 M phosphate buffer (pH 7) and 1 ml. was diluted into a further 10 ml. buffer before use. N-ethylmaleimide was added 4–6 min. before irradiation except where otherwise stated. The suspensions were irradiated at room temperature under aerated or anoxic (nitrogen bubbling) conditions with gamma-rays from a 1,000-curie cobalt-60 source. The dose-rate was approximately 300 krad/hr. Surface plate counts on 'Oxoid' nutrient agar were made before and after irradiation, and the colonies were counted after 48 hr. incubation at 30° C.

The survival curves in the presence and absence of 0.001 M N-ethylmaleimide are shown in Fig. 1, and it can be seen that a pronounced sensitization occurred. Under nitrogen there was approximately a two-fold difference in the sensitivity of control and treated cells, although under air sensitization was not so marked especially at the lower levels of irradiation. Incubation with 0.001 M N-ethylmaleimide for a period of 20 min. immediately after irradiation did not enhance radiation damage, nor was it toxic to unirradiated cells at this concentration, indicating that it is a true sensitizing agent. The shape of the aerobic curve suggested that pre-incubation with the sensitizing agent for several minutes might be necessary for the attainment of the full effect (under nitrogen there was always 6 min. incubation before

Fig. 1. Effect of 0.001 M N-ethylmaleimide on the inactivation of *Escherichia coli* strain B/r by gamma-radiation. ●, Control; ○, N-ethylmaleimide added before irradiation; □, N-ethylmaleimide added after irradiation for 20 min.

irradiation while oxygen was removed). Various times of pre-incubation were therefore tried, and it was found that a definite sensitization was observed with pre-incubation for as little as 1 min. The full effect was attained within 5 min. and there was no increase in sensitization when the pre-incubation period was increased from 5 to 15 min.

The sensitizing action of this compound might be due to its ability to combine with sulphydryl groups. Compounds with this property do not appear to have been reported before as sensitizers of bacteria to irradiation under controlled gas conditions, although halogen acetates which also combine with sulphydryl groups have been reported as sensitizing agents for mammals¹⁻³. Kiga and his co-authors⁴ reported that maleic acid enhanced the effect of X-rays on *Saccharomyces ellipsoideus*. If, however, the inhibitory action of maleic acid on respiratory enzymes influenced the concentration of dissolved oxygen, then the observed enhancement in this instance could be due to an effect of oxygen rather than to maleic acid directly. It may be significant that experiments in this Laboratory under controlled gas conditions have failed to show any sensitizing action of maleic acid on *E. coli* strain B/r.

I wish to thank Mr. M. J. Ashwood-Smith for discussions during the early part of this work.

PHYSIOLOGY

Analysis of the Junction Potential of a Small Nerve

Fatt and Katz¹ demonstrated with the aid of an intracellular microelectrode that the end-plate potential was produced in the region of the motor end-plate by a sudden and transient reduction in the membrane potential as a result of neuromuscular transmitter action. They further pointed out that the prolonged decline of the end-plate potential was almost exponential and was determined by the electrical properties of the resting muscle membrane. An equivalent circuit of the resting muscle membrane is represented as a condenser in parallel with a battery (membrane potential) with a series resistance (membrane resistance). In the active phase of the end-plate potential, the membrane resistance at the junctional region is suddenly reduced by the transmitter action, that is, the muscle membrane is shortened by a shunting resistance¹. To demonstrate the active process of the end-plate potential, Takeuchi and Takeuchi² and Oomura and Tomita^{3,4} recorded a current flowing through the end-plate region of the muscle membrane by stimulating the nerve under conditions where the membrane potential was kept at the resting level, using the voltage-clamp technique^{5,6}. On the other hand, the small motor nerve fibres which innervate the slow muscle fibres and relate to the tonic function in the maintenance of posture, also produce the junction potential of the small nerve at the junction region by its stimulation⁷. A distinctive feature of this junction potential is that it displays two phases with a terminal phase of hyperpolarization⁷. In the present work an attempt has been made to analyse the mechanism of production of the junction potential of the small nerve, using the voltage-clamp technique.

Two microelectrodes were inserted (within 50 μ of each other) into a slow muscle fibre, one for recording the membrane potential and the other for passing current through the membrane. For the voltage-clamp experiment, a negative feedback amplifier system was connected to the microelectrodes to keep the membrane potential constant at the resting level. Junction potentials were evoked by selectively stimulating the small motor axons⁸. All experiments were carried out on isolated biceps muscles of bullfrogs (*Rana catesbeiana*), in a cold room at 7° C. in summer.

The membrane potential of the resting slow muscle fibre ranged between 40 and 70 mV., the inside of the muscle being negative. In this experiment the time-constant of the resting muscle membrane, resistance multiplied by capacity, ranged from 500 to 1,000 m.sec. Occasionally after the insertion of the recording electrode at the region of the junction of the muscle a simple monophasic form of the small-nerve junction potential (see Figs. 1 and 2) was obtained. The time-course of the falling phase of this potential was roughly exponential, the 1/e decay time being approximately 800 m.sec. (note that this value is comparable with that of the time constant of the resting muscle membrane). The simple monophasic form soon (within 1 or 2 sec.) changed into the diphasic decay form (Fig. 3), which is characteristic of hyperpolarization, being accompanied by a 10 per cent reduction of the membrane potential. When the negativity of the membrane

Fig. 1. Junction potentials of small-nerve with the monophasic form recorded intracellularly from a biceps muscle of a bullfrog (membrane resting potential, -65 mV.). Fig. 2, the same as 1, but from a different fibre (resting potential, -60 mV.). Fig. 3, junction potentials of small-nerve with a diphasic form (resting potential, -54 mV.). This characteristic form was changed from the monophasic one of Fig. 2. Upward deflection shows the depolarization and downward one the hyperpolarization. Fig. 4, the current (upper oscilloscope tracing) obtained at the same junction from which Fig. 3 was taken under the clamped condition. The membrane potential was kept at the resting level (-54 mV.) as shown by the lower tracing. Calibrations are 40 mV. for potential, 2×10^{-8} amp. for current. Horizontal bar, 500 m.sec. Temperature, 7° C.

potential was increased by a steady inward current before applying a stimulation, the junction potential of the small nerve with the diphasic form (Fig. 3) changed to the monophasic form (Fig. 2). We therefore think that the small-nerve junction potential is of the monophasic form (Figs. 1 and 2), where the decline of the potential is determined by the electrical properties of the resting membrane as is the end-plate potential, and that the diphasic decay is due to a mechanism developed by injury of the muscle membrane at the junction region caused by impalement by the electrode.

The current showing the active phase of the small-nerve junction potential of the small nerve was obtained by the voltage-clamp experiment. The upper tracing of Fig. 4 shows the clamped current flowing through the junction of the muscle at the same junction where the record in Fig. 3 was taken. This current was obtained by stimulating the nerve under the condition where the membrane potential was kept at the resting level, as shown by the lower oscilloscope tracing of Fig. 4. It declined monophasically with an almost exponential time course, although the small-nerve junction potential on Fig. 3 decayed diphasically, and the current corresponding to the phase of hyperpolarization of the junction potential was not shown in the current observed. The clamped current represents the active phase, that is, the temporal change of the shunting resistance across the muscle membrane at the junction region (similar to the case of the current obtained at the end-plate region). The time-course of the clamped current was not altered significantly by making the membrane potential more negative, while the time course of the small-nerve junction potential changed from the diphasic to the monophasic form.

The intensity and the time-course of the clamped current and the amplitude of the small-nerve junction potential were increased by adding a small amount

of tetraethylammonium chloride or eserine to the Ringer solution bath. However, the intensity of the clamped current was not altered by excess calcium ions, while the amplitude of the small-nerve junction potential was increased. Since the clamped current represents the active process at the junction region, increases of both potential and current may indicate an increase in the amount of the transmitter substance liberated and the prolongation of its action. The increase of the junction potential without increase of the clamped current may not involve these mechanisms, but may be due to the increase of the resistance of the resting muscle membrane by calcium.

This work was supported by a grant from the Ministry of Education of Japan and from the Rockefeller Foundation (GA BMR 5748). We are indebted to Prof. N. Toida for his criticism.

Cell Proliferation in Precancerous Liver: Linear Growth Curve

In extending our recently published work on cell growth and the development of tumours¹, we have observed that in the livers of rats fed 2-acetylaminofluorene the cell proliferation continues at a constant rate during the pre-cancerous period and does not decrease as we had at first supposed. Such continuous increase in a cell population at a constant rate constitutes a most unusual form of growth, and it affords an important insight into the dynamics of cell proliferation in a pre-neoplastic tissue.

As in the previous experiments¹, male rats of the Holtzman and Sprague-Dawley strains were fed continuously a commercial grain diet containing 2-acetylaminofluorene. In several of our experiments we have measured the consumption of 2-acetylaminofluorene, and have found it to be quite constant throughout the experiment. Eight similar experiments have been carried out to date, involving a total of about 400 rats; from these experiments, one has been selected for presentation in Figs. 1-3. In this experiment the initial body-weight of the animals was 135 gm., and the concentration of 2-acetylaminofluorene in the diet was 0.06 per cent. For each experimental point, 4 rats were chosen with body-weights representative of the average and range of body-weights of the whole experimental group. They were killed with ether, and the livers were removed and perfused immediately. Then the livers were pressed through a plastic tissue mincer and the mince from 4 livers was mixed carefully; an aliquot of this mixed mince was then homogenized in 0.88 M sucrose. The nuclei were counted in a haemocytometer after

Fig. 1. Changes in the total number of liver cells during the continuous administration of 2-acetylaminofluorene in the diet

dilution of the sucrose homogenate 1:40 in 3 per cent acetic acid containing a nuclear stain; under these conditions the nuclei are well dispersed and easily counted. From the known concentration of liver in the homogenate and the known dilution of the homogenate in the counting fluid, the number of nuclei per gram of fresh liver and per whole liver was calculated. The protein nitrogen and nucleic acids of the homogenate were also determined^{2,3}, and the analytical results were expressed in terms of the average whole liver by multiplying the values obtained per gram by the fresh weight of the livers.

Fig. 1 shows the changes observed in the total number of liver cells. As we reported in our recent paper¹, the number of cells per average liver remained unchanged for several weeks after the administration of 2-acetylaminofluorene was started. Two of the experimental animals died during the fifth week of the experiment, in agreement with our previous findings¹. The early period of cell constancy was followed by a rapid increase in the number of liver cells, with the result that by 12 weeks in this experiment the number of liver cells had increased about three-fold. The cell proliferation of this second period was essentially linear; the points fit well the straight line drawn through them by the method of least squares. The slope of the line is 0.268; this means that on the average 268×10^6 new cells were produced every week. This linear growth has been maintained in other experiments through the twenty-third week, or up to the time at which tumours were beginning to appear, and hence is characteristic of the entire pre-cancerous period.

Figs. 2 and 3 show the corresponding changes in the protein nitrogen and ribonucleic acid in the same livers. After an early period in which some loss of these biochemical constituents occurred, they also increased in a straight line. The protein nitrogen increased at a constant rate of about 28 mgm. per week, and the ribonucleic acid at a constant rate of about 9 mgm. per week.

It was an unexpected finding that the number of liver cells increased at a constant rate. However, this linear growth has now been demonstrated in all of a current total of 8 different groups of experimental animals. Cell proliferation at a constant, and thus

Fig. 2. Changes in the total quantity of protein nitrogen in the liver during the continuous administration of 2-acetylaminofluorene in the diet

Fig. 3. Changes in the total quantity of ribonucleic acid in the liver during the continuous administration of 2-acetylaminofluorene in the diet

statistically linear-rate can be assumed to occur normally in such tissues as intestinal epithelium and the blood-forming organs, where the total population remains essentially constant over long periods of time. In these tissues cell proliferation is not autonomous, but is under the control of regulatory mechanisms in the animal that assure the delicate compensatory adjustment of the production of new cells to the constant loss of mature cells from the system. The linear cell proliferation produced in the liver by 2-acetylaminofluorene is probably a compensatory phenomenon also. However, it cannot be compensatory to a loss of cells since the number of cells is actually increasing, and there is no evidence at any time of extensive necrosis in these livers^{4,5}. This proliferation of liver cells might, however, be compensating a loss of some functional capacity of the liver that is inactivated or destroyed by 2-acetylaminofluorene and that is essential to the survival of the

animal (usually a few of the animals die at the time the cell proliferation starts in the survivors¹). The latent period preceding the onset of cell proliferation is to be expected if the functional capacity involved is normally present in an amount greater than the minimum necessary for survival. Although the exact mechanism is not understood at present, it is evident that the administration of 2-acetylaminofluorene in the diet at a constant rate produces a proliferation of liver cells at a constant rate, and it appears therefore that this cell proliferation represents a quantitative response to the amount of 2-acetylaminofluorene actually being consumed.

The relation of the large-scale proliferation of liver cells to the production of the few successful malignant cells which ultimately become tumours remains to be explained.

This work was done under the auspices of the U.S. Atomic Energy Commission.

Acetate Tolerance in the Young Lamb

RECENT work has shown that alterations can be produced in the tolerance to acetate and glucose in adult sheep by varying the nature of the diet^{1,2}. With the inclusion of maize in a diet of lucerne and wheaten chaff the response of an adult sheep to an intravenous injection of glucose or acetate simulates much more closely the rapid rate of removal of these substances from the vascular system characteristic of a monogastric animal¹.

There are now many observations on the glucose tolerance^{3,4}, insulin sensitivity⁵, hexokinase activity⁶, and blood volatile fatty acids⁷ in sheep and lambs which indicate that many aspects of the metabolism of carbohydrate in young lambs differ from those of adult sheep.

In view of these observations, the response to injected acetate in the very young lamb was determined and followed at intervals for a period of four months after birth. Five Merino wether lambs running with their dams on a mixed pasture were used. At intervals of a few days an injection of acetic acid neutralized to pH 7.0 with sodium hydroxide (5 m.moles acetic/kgm. body-weight) was given into the jugular vein and samples of blood obtained at 2, 15, 30 and 60 min. after the injection. The concentration of total volatile fatty acid was determined in each sample and also in urine collected over several hours by attaching a small rubber bag to the abdomen of the animal.

The results from two of the lambs, typical of the whole series, are presented in Table 1 and clearly indicate that the new-born lamb can very rapidly remove injected acetate from the blood stream. Analyses made on blood taken before the acetate injection showed a concentration of volatile fatty acid within the range 0.2-0.6 m.mole/l. for lambs of all ages; this range has also been observed for adult sheep feeding on green pasture.

Table 1. CONCENTRATION OF VOLATILE FATTY ACIDS IN BLOOD (m.moles/l.) AFTER THE INJECTION OF ACETATE (5 m.moles/kgm.)

Age	Lamb No. 18			Lamb No. 21		
	Min. after acetate injection			Min. after acetate injection		
	2	15	30	2	15	30
1-2 days	8.26	3.32	0.08	8.05	3.24	0.48
6-7 days	8.46	2.32	0.06	9.14	3.31	0.20
2-3 weeks	11.16	2.45	0.37	9.00	2.09	0.44
4-6 weeks	10.58	4.43	0.66	10.06	4.42	0.39
10-12 weeks	11.16	4.57	1.08	11.44	6.51	2.03
14-16 weeks	13.66	6.48	3.97	12.95	5.91	3.60
Adult	21.63	10.13	4.36	20.43	7.00	3.97

During the first four weeks of life all injected acetate was removed from the blood by the end of 30 min. whereas with older lambs and adult sheep a period of up to 60 min. was observed before the pre-injection level was reached. That this rapid rate of removal in the young lamb was not associated with a low renal threshold was indicated by the very small excretion of acetate during a 6-hr. period following the acetate injection (1-2 m.moles or less than 4 per cent of the injected dose).

It is thus apparent that as the lamb becomes older its tolerance to acetate alters until at approximately four months of age the rate of disappearance of injected acetate is similar to that of the adult sheep. This gradual change is comparable with the change which takes place in glucose tolerance and insulin sensitivity. Some other parameters, however, such as alterations in hexokinase activity⁶ and liver coenzyme A-levels⁸, change much more rapidly and at an earlier age.

These observations are of interest in that they add further support to the hypothesis that the young lamb behaves in many respects like a non-ruminant, and only gradually develops some of the metabolic characteristics of the adult sheep.

Hydrothermal Denaturation of Collagen

In a recent communication by Rigby and Spikes¹, structural breakdown of collagen is considered to be possible on its prolonged contact with water at a temperature as low as 40° C. Such alterations of human collagen are believed to be involved in the manifestation of rheumatic symptoms. Evidently, the authors are not aware of the fact that experimental evidence for the occurrence of gradual shrinkage and labilization of mammalian collagen in water at a temperature of 40-45° C. is on record. In

the monograph² to which the authors refer in connexion with the correlation of hydroxyproline content of various collagens and their temperature of instantaneous shrinkage, T_s , work is cited³ proving the rupture of intermolecular hydrogen bridges of collagen in the temperature-range mentioned (denaturation). Table 16 in the accompanying monograph⁴ supplies substantiation. Hence, the speculative feature of their premise is removed.

By immersion of pieces of calf-skin (middle layer of corium) in water, covered with toluene, at 45° C. for one week, some 8 per cent of the protein was solubilized. The T_s of the corium was lowered from 67° C. to 56° C. The trypsin treatment (for method, see ref. 5) of the original corium resulted in 0.2 per cent degradation, whereas the corresponding figure for the corium treated with warm water was about 10 per cent. These findings indicate a marked labilization of the collagen on prolonged action of water at 45° C.

The main evidence referred to²⁻⁴ was obtained by a method which was devised by me and applied in an extensive series of investigations of the effect of denaturation of collagen, by hydrogen-bond breakers and hydrothermal forces, on its reactivity and properties⁶. It relies on the fact that, by denaturation of the skin protein, its hydrogen-bonding capacity is drastically increased. However, its affinity for agents which react with the protein by electrovalent forces exclusively is not altered. Such agents are 0.1 N hydrochloric acid and cationic chromium complexes⁶, indicating the non-participation of ionic protein groups in this denaturation. For chromium complexes of high degree of aggregation, partly in the non-ionic state (extremely basic chlorides and perchlorates, as well as sulphito-chromium-sulphates), the keto-imide groups serve as the chief binding sites. By breaking or rupture of the hydrogen bridges between adjacent keto-imide groups, resulting from steric effects induced by the shrinkage of the collagen, new binding sites on these uncompensated groups, and possibly on some hydroxy groups, are made available for reaction. Thus, corium which had undergone pretreatment in water at 45° C. fixed 7.4 m.equivalents of chromium per gm. of collagen irreversibly from a solution of 33 per cent acid chromium perchlorate⁷, while original collagen combined with 5.1 m.equivalents of chromium only. For the sulphito-chromium sulphate⁸, the corresponding figures were 11.7 and 8.0.

Supporting evidence for the breaking of hydrogen bridges, by the unfavourable steric condition produced by the shrinkage of collagen, supplies data on the fixation of polyphenols (vegetable tannins), which for their main fixation by collagen depend on the function of the keto-imide groups as acceptors for hydrogen bonds donated by the phenolic groups^{6,9}; one of the main pieces of evidence being their binding by polyamides⁹. In the present instance, with mimosa bark tannins at a final pH of 5.0, the collagen treated with warm water fixed 87 per cent of its weight of these tannins irreversibly, while the original collagen combined with 66 per cent of tannins.

These results prove the occurrence of marked disorganization and impaired stability of the skin protein by water at 45° C., or at a temperature some 25° C. below the normal T_s of mammalian corium. This gradual shrinkage differs only in degree from the instantaneous shrinkage; for example, in alterations in stability and reactivity of the collagen. In

the present example, about 40 per cent of the maximum effect of the augmentation of the co-ordination potency due to complete shrinkage of collagen resulted.

These investigations were carried out at a time when the present, simple but powerful, techniques in protein chemistry were not available. Then, the nature of the degradation products could not be investigated. In the light of recent findings, polypeptides containing a disproportionately large amount of hydroxyproline residues are released on the shrinkage of young collagen¹¹. The content of this important amino-acid should then be lowered by denaturation, conforming to the view of Rigby and Spikes¹—a fact apparently of importance for their main problem. References given in footnote 11 should be noted in this context.

We are pleased to find that Prof. Gustavson has further chemical evidence which supports our speculations. We were aware of the references^{1,2} listed by Prof. Gustavson when referring to the gradual shrinkage of collagen at temperatures below the instantaneous shrinkage temperature. However, we took these observations to be complementary to the physical experiments of Weir³, which show the 'rate process' nature of the shrinkage phenomenon and to which we did refer.

PATHOLOGY

Carcinogenic Action of Diazomethane and of Nitroso-N-methyl Urethane

THE transformation of inactive or slightly active compounds into effective carcinogens by O-methylation has been discussed previously¹, and it was suggested that endogenous carcinogens may possibly be formed by alkylation of normal cell constituents in

Fig. 1. Lung of an A/2G male mouse that died after 11.5 months of application of ethereal diazomethane to the skin, showing one large and one small adenomata. ($\times 3$)

the body. Such a mechanism could account also for the carcinogenic effects of radiation and of remotely acting agents, such as the azo-dyes, ethionine, etc., which may give rise to alkyl radicals in the body.

To test this hypothesis, diazomethane was chosen as a suitable alkylating agent. It is able to effect methylation under physiological conditions of pH and temperature, evolving nitrogen as the only other product. Diazomethane is a gas and is usually obtained in ethereal solutions by the decomposition with alkali of some nitroso-N-methyl compounds². Such compounds may possibly give rise to diazomethane or methylene radicals enzymatically in the animal body, without the need of alkali and drastic conditions. The commercially available nitroso-N-methyl-urethane was used for the preparation of diazomethane, and was itself tested for carcinogenic activity.

The results of the exploratory experiments proved sufficiently encouraging to warrant reporting at the present stage.

Male mice and rats, 1-3 months old, were used. Mice of the A/2G strain were obtained from the Laboratory Animals Centre, Carshalton; Swiss albino mice were obtained from the National Institute for Medical Research, Mill Hill; rats were Wistar, bred locally from the Porton strain. All the animals were housed in metal cages and given the Medical Research Council diet 41B and water *ad libitum*.

Diazomethane was prepared according to Bachmann *et al.*³. Its ethereal solutions were kept at -5°C . for periods up to three months, and the concentration, estimated by the benzoic acid method, varied between 3.3 and 0.1 mgm./ml. The ethereal solution was applied from a dropping pipette to the shaved skin of the interscapular region of twelve A/2G mice, five times weekly. Eight mice survived more than five months of such treatment, but all these died within twelve months with lung adenomata, often multiple and of considerable size (Fig. 1). No abnormalities were present on the skin at the site of application, possibly because of the protective action of keratin.

The effect of inhalation of diazomethane was then examined using twelve A/2G and six Swiss mice, and six Wistar rats. For this purpose the animals were placed in a desiccator, 6,250 ml. capacity (in groups comprising six mice or two to three rats at a time) and 1 ml. of ethereal diazomethane solution was

introduced from a syringe through a plastic cover replacing the stopper in the lid. Control animals (twelve mice of the A/2G strain and six Swiss mice, and two Wistar rats) were similarly exposed to ether only. The times of exposure were 1 or 2 min., twice weekly, for six months. When an animal appeared in poor condition, its treatment was terminated earlier. All the animals exposed to diazomethane by inhalation developed lung lesions, some dying acutely of lung oedema. Those dying later all had lungs grossly deformed, nodular and brownish.

All the mice of A/2G strain died within seven and a half months, and the majority had lung adenomata. Mice of the A/2G strain develop spontaneous lung adenomata in old age. However, in A/2G mice treated with diazomethane the incidence of these tumours was greatly accelerated. Only one or two small adenomata were found in the control A/2G mice killed at comparable age. Shimkin and Lorenz⁴ observed similar acceleration of the development of adenomata in mice of the A strain injected intravenously with carcinogenic polycyclic hydrocarbons, and considered this as evidence of carcinogenic activity for the lung.

The lesions in the Wistar rats and in the Swiss mice affected mainly the bronchii. These became more prominent with time. Animals were killed at intervals even when still in good condition, in order to observe the evolution of the lesions. The last mouse and the last rat were killed eleven months after the beginning of treatment and about 5 months after its termination. The rat had a whitish big cellular tumour 2-3 cm. diameter in the right lobe of the lung, adhering to the chest wall. All the other lobes of the lung were studded with smaller whitish nodules, 1-5 mm. in diameter. Similar whitish nodules covered, and adhered to, the inner surface of the chest; they were particularly numerous at the upper right side and on the diaphragm. The organs in the peritoneal cavity did not appear grossly infiltrated by the tumour. Microscopically, the tumour and the disseminated nodules proved to be a carcinoma of the bronchial epithelium containing many mitotic figures. The control Swiss mice and Wistar rats, which were exposed to ether only, did not show any significant abnormalities when killed at the time of death of the last experimental animals.

Nitroso-N-methyl urethane was administered orally to Wistar rats. A single dose of 0.1-0.2 ml. of a 20 per cent or 2.5 per cent solution in 50 per cent or 5 per cent aqueous alcohol, respectively, was given by stomach tube to two groups of 10 and 6 rats respectively. The animals were then left without further treatment. The rats which received the 20 per cent solution all died within two to three days. Their lungs were dark red, some showed subcutaneous oedema, they had enlarged pale livers, and all had stomachs distended with fluid content, often containing blood, and haemorrhagic petechiae were present on the stomach walls. Microscopically, the livers showed necrosis confined to the portal areas, and the lungs, perivascular and peribronchial oedema and haemorrhage into the alveoli.

Rats which were given the lower dosage survived from 10 days to 20 months. Their livers appeared normal, and lesions, if any, were confined to their stomachs and lungs. One of the rats which died 19 months after a single dose of the compound had a large, irregular, whitish mass in the abdominal cavity, involving the stomach, small intestines and

Fig. 2. Stomach of a male rat that died 19 months after a single oral dose (50 mgm./kgm. body-weight) of nitroso-N-methyl-urethane. ($\times 1.5$)

Fig. 3. The same rat as Fig. 2, section showing squamous carcinoma of the fore-stomach. Haematoxylin and eosin. ($\times 37.5$)

spleen. There were also numerous nodules spread throughout the peritoneal cavity. Unfortunately, there was severe postmortem change, but microscopic examination indicated squamous carcinoma of the stomach with peritoneal spread (Figs. 2 and 3).

In our colony no stomach tumours have been seen at autopsy of several thousand treated and untreated rats. There was also no reason to suspect vitamin A deficiency, therefore the stomach tumour was probably caused by nitroso-N-methyl-urethane.

I am grateful to Dr. P. N. Magee for the microscopic evaluation of the various lesions, which will be described in detail elsewhere, and to Dr. J. M. Barnes for his interest. I also thank Mr. M. R. Greenwood for valuable technical assistance, and Mr. R. F. Legg for the photographs.

Serum Protein Abnormalities in 'Runted' Albino Rats

In the course of previous investigations, we have observed that when either normal or neoplastic tissues of mouse origin are injected into new-born albino CEN rats (Carworth-Wistar origin) occasional animals will develop a wasting disease characterized by roughened scaly skin, sparse hair growth, failure to gain weight normally, and sometimes actual loss of weight^{1,2}. This condition usually appears during the first 7-14 days of life and many of the animals so afflicted succumb within a few days. Others survive this crisis and live for at least 35 days. Apart from the sparse hair and stunted growth, these survivors are apparently normal.

The same phenomenon is occasionally observed following intraperitoneal inoculation of normal adult DBA/2 mouse spleen cells into new-born albino

rats¹; but it occurs much more frequently after subcutaneous, intraperitoneal² or intracerebral injection of one of several transplantable mouse tumours into this host. The transplantable mouse tumours so far associated with this subsequent wasting disease are the Ehrlich ascites tumour, the lymphoma L4946, the lymphoma P1534, the lymphosarcoma 6C3HED, the mammary carcinoma BW10232, the melanoma S91 and the neuroblastoma C1300. Many of the young rats appeared to expire as a direct result of the growth of the Ehrlich ascites tumour, the lymphoma P1534, the lymphoma L4946 and the lymphosarcoma 6C3HED; but there were individuals in which the wasting condition became evident during or after tumour regression. Furthermore, this disorder occurred rather frequently after inoculation of the mammary carcinoma and the melanoma, neither of which ever demonstrated palpable growth.

This 'runted' rat is interesting because it is grossly similar to the runts described in homologous transplantation studies³⁻⁵. Autopsied rats dying with this disorder reveal some of the general characteristics noted by Billingham and Brent³; the spleen is small, the thymus absent or quite small, the mesenteric lymph node usually absent and lymphogenous tissue generally reduced. When we exclude from consideration those rats appearing under-developed at birth or those which were survivors of litters having a high mortality during the first few days of life, only 6 animals which might be grossly classified as runts have been encountered in 251 rats injected with control Tyrode solution or not injected at all. Unfortunately, these animals were not autopsied, since the significance of this condition had not then been realized. In contrast, 15 of 23 rats inoculated at birth with the mammary carcinoma BW10232 developed the runting disease.

Since it is probable that other abnormalities of the reticulo-endothelial system are present in the runted animals, we have begun an intensive investigation of the serum proteins. So far this investigation is limited to those animals surviving the first 5 weeks of life. At this age, normal litter mates raised under identical conditions weigh 75-100 gm., whereas the runts weigh 35-55 gm. This communication constitutes a preliminary report on the serum protein fractions in these animals.

Tissue suspensions of mouse melanoma S91, mammary carcinoma BW10232, and normal DBA/2 spleens were prepared by mincing with fine dissecting scissors followed by gentle manipulation in a glass homogenizer to which Tyrode solution had been added. New-born CFN rats were injected with approximately 20×10^6 cells from one of these suspensions. The normal spleen cells were administered intraperitoneally, whereas the tumour cells were injected subcutaneously. Control groups of rats having received either 0.1 ml. of Tyrode solution or no injection at all were included. The animals were inspected at intervals of 2-4 days and were weighed each week.

Following the weighing at 5 weeks of age, blood was drawn by cardiac puncture, the serum collected and paper electrophoresis of the serum proteins carried out with a Spinco model RB electrophoresis apparatus. Serum aliquots of 0.008 ml. were subjected to electrophoresis at 4.0 m.amp./cell for 18 hr. at room temperature. The strips were dried, stained, and analysed with a Model RB analytrol.

Table 1. SERUM PROTEIN FRACTIONS IN 5-WEEK-OLD NORMAL AND 'RUNTED' ALBINO RATS INJECTED AT BIRTH WITH MOUSE TISSUES

Material injected at birth	No. tested	Mean weight (gm.)	Serum protein fraction			
			Albumin (per cent)	α_1 - and α_2 - (per cent)	β - (per cent)	γ - (per cent)
None	15	88	60.6	20.8	14.7	3.9
Tyrode solution*	9	90	60.2	20.9	14.6	4.3
Adult mouse spleen†	6	84	58.2	21.7	15.8	4.3
Mammary carcinoma‡	3	89	60.5	20.0	14.8	4.7
Melanoma§	4	88	61.9	20.8	14.0	3.3
Adult mouse spleen†	7	45	45.0	20.3	21.0	13.7
Mammary carcinoma‡	3	31	48.1	20.6	18.6	12.7
Melanoma§	3	42	48.7	21.4	16.9	13.0

* Tyrode solution is utilized in preparation of the cell suspensions.

† Obtained from 12- to 16-week-old DBA/2 female mice.

‡ Mammary carcinoma, BW10232 indigenous to the C57BL/6 strain of mice.

§ Melanoma S91 indigenous to the DBA/2 strain of mice.

The serum protein fractions are indicated in Table 1. It can be seen that the β - and particularly the γ -globulins are elevated in those rats with subnormal weight. As Figs. 1 and 2 further indicate, the correlation is not with the kind of tissue injected at birth, but rather with the fact that a runt was produced by 5 weeks of age. For example, approximately 20×10^6 normal adult DBA/2 mouse spleen cells were injected intraperitoneally at birth into two rats, yet, as shown in Fig. 1, only the runt had an increased percentage of β - and γ -globulins. Furthermore, when melanoma S91 cells were inoculated subcutaneously into another pair as illustrated in Fig. 2, the increased globulin percentages were produced in the runt, but not in the normal animals.

Fig. 1. Paper electrophoresis of serum obtained from 5-week-old albino rats inoculated at birth with normal adult mouse spleen cells. Note the decreased albumin and increased β - and γ -globulin percentages in the animal with subnormal weight.

Fig. 2. Paper electrophoresis of serum obtained from 5-week-old albino rats inoculated at birth with melanoma S91 cells. Note the decreased albumin and increased β - and γ -globulin percentages in the animal with subnormal weight.

The 6 untreated animals that died with the gross characteristics of wasting prevent us from concluding with certainty that the wasting disease in the young albino rat is directly attributable to the injection of normal or neoplastic mouse cells. We share with Billingham and Silvers⁴ the opinion that in some instances the effect of this inoculation may rather be to aggravate or enhance another, as yet unrecognized, factor. These authors, moreover, have described a runt rat which follows the injection of homologous adult rat spleen or bone marrow cells. The most obvious feature of the homologous disease so produced was a severe dermatitis. Anderson *et al.*⁵, however, have described runt disease produced by the intravenous injection of homologous thoracic duct lymphocytes into albino rats without reporting any skin involvement. We have not observed severe dermatitis in the runt disease of our albino rats following the inoculation of heterologous mouse tissues. Although the explanation of these discrepancies may lie in the fact that different strains of rats are utilized by each group, we must consider the possibility that different etiological mechanisms are operating in the three experimental systems. Nevertheless, our results indicate that whatever the etiology of the runt encountered in our work, the production of an unusually high percentage of γ - and β -globulins results.

Of particular interest is the recent work of Gengozian⁶, who reports a consistent elevation in the lipoproteins (γ - and β -globulins) in the radiation-induced rat-to-mouse chimera. This abnormally high fraction seems to be produced by the mouse host and not by the donor rat tissues. Using similar techniques, we intend to measure quantitative changes in proteins with the view of determining directly whether the higher percentages of β - and γ -globulins observed by us are of host rat or donor mouse origin.

BIOLOGY

Occurrence and Distribution of Cytochrome $a + a_3$ in Plant Cells

Cytochrome a occurs in plant materials only in very low concentrations and its activity is rapidly lost in homogenates kept at room temperature. Numerous visual observations of its presumed α -band have nevertheless been recorded for a variety of plant materials¹⁻⁵. The reported values have a rather wide scatter lying between $\lambda = 600$ and $605 \text{ m}\mu$. Recently, cytochrome a has also been recorded spectrophotometrically, but still with an equally wide scatter of the position of the α -band⁶⁻¹⁰. Observations tending to show the presence of the a_3 compound in plant materials have so far been very few.

Embryos of wheat appear to contain relatively large amounts of cytochrome a and its α -band appears stronger in comparison with the α -bands of cytochromes b and c than is usual in visual low-dispersion spectra. The spectrum is best observed in a mitochondrial pellet of the consistency of a thick paste.

Mitochondria were extracted by conventional methods from viable wheat germ freed from endosperm particles by flotation on a mixture of cyclohexane and carbon tetrachloride (10:25 v/v). The mitochondrial pellet was finally centrifuged down at $10,000g$ from a medium containing 0.2 M sucrose, 0.05 M phosphate pH 7.2 and 0.001 M magnesium sulphate, and examined in a layer about 10 mm. deep with a Beck microspectroscope. After reduction with sodium ascorbate a well-defined absorption band was visible at $\lambda = 600 \text{ m}\mu$ and another at $552 \text{ m}\mu$. They were still visible after 24 hr. in a deep freeze when again reduced with dithionite. After each reduction the cuvette containing the pellet was flushed out with carbon monoxide and the spectrum re-examined shortly after. The band at $600 \text{ m}\mu$ moved to $590\text{--}592 \text{ m}\mu$, while that at $552 \text{ m}\mu$ remained unaltered.

Attempts to confirm these observations with a spectrophotometer were at first frustrated by the very high degree of light scatter caused by the mitochondria in suspension. Even after addition of 0.025 gm. cytochrome c to 3.0 ml. of mitochondrial suspension no definite absorption band was recorded. Effective observation was achieved by the following method using a Unicam SP 500 spectrophotometer with a SZG 500 photomultiplier attachment. The mitochondria were re-suspended in the sucrose-phosphate medium and subjected to ultrasonic vibration (5,000 cycles per min.) for 20 min. and then centrifuged down at $100,000g$ for 30 min. The pellet was re-suspended in 2 ml. of 60 per cent glycerol + 40 per cent sucrose-phosphate medium. The cuvette containing the suspension was placed as close to the photomultiplier unit as the construction of the apparatus would allow (about 1 cm. distance) instead of in its normal position by the light slit. With these precautions absorption curves could be recorded between wave-lengths $580 \text{ m}\mu$ and $610 \text{ m}\mu$. The continuous curve in Fig. 1 shows the difference in absorption by the mitochondrial suspension before and after reduction with a trace of dithionite. The usual α -peak is shown at $602 \text{ m}\mu$ and a secondary peak at $594 \text{ m}\mu$ due to reduced peroxidase¹¹. After treatment with carbon monoxide the absorption-difference curve was changed to that shown by the broken line.

Fig. 1. —, no carbon monoxide; ---, plus carbon monoxide

revealing the formation of the cytochrome a_3 -carbon monoxide compound with an absorption maximum at about 592 $m\mu$. At the same time a corresponding change occurred in the deep blue region of the spectrum, a small peak appearing at 424–426 $m\mu$, attributable to the γ -band of the cytochrome a_3 -carbon monoxide compound.

Electronmicrographs of thin sections of the mitochondrial pellets treated with osmium tetroxide have been prepared for us by Dr. M. S. C. Birbeck. The mitochondria show the normal type of structure as seen in thin sections of tissue. Broken mitochondria and other detritus are rare. After vibration the walls and lamellae were entirely broken down into a fairly uniform mass of particles with a mean diameter of about 30 $m\mu$. Any soluble contents of the mitochondria would, of course, have been removed by the final centrifugation.

The above observations seem to make it clear that both components of the cytochrome $a + a_3$ complex are present in the cells of wheat embryos. Their spectra can only be clearly observed after the cell components other than mitochondria have been discarded, and no bands have been observed in the supernatant after the mitochondria have been removed. Disintegration of the mitochondria shows that the two components are both attached to the mitochondrial membranes and are not discarded with the internal fluids.

Repeated spectroscopic investigation of preparations of isolated nuclei from the same tissues have failed to reveal any bands attributable to any of the respiratory cytochromes. None was detectable in nuclear suspensions having twenty times as much total nitrogen as that required to give visible bands with mitochondria. The embryonic cells investigated did not contain chloroplasts; but it has already been shown that the chloroplasts of green cells do not contain any detectable cytochromes other than b_6 and f (refs. 12, 13). It appears probable that the cytochrome $a + a_3$ complex occurs in higher plant cells, as previously shown for others, only on the membranes of the mitochondria.

A New Type of Citrus Fruit Rot caused by *P. italicum* Wehmer

DURING the past five years, while engaged on the examination of arrivals of Israeli citrus fruit in Britain and on the Continent, an unfamiliar type of dark red varying to bronze-red mould rot on oranges

and grapefruit was occasionally found. So far as I am aware this rot has not been previously recorded.

Microscopic examination of the affected rind tissue revealed fungal penetration, and that many of the fungal cells within the tissue and on the rind surface had reddish pigmented contents. Sub-plants on common nutrient agar media invariably produced the blue mould fungus *Penicillium italicum*, yet it seemed inconceivable that the citrus blue mould rot fungus could be the causal organism of this new type of fruit rot.

The new fruit rot is of minor economic significance, as demonstrated in Table 1, which records the incidence of the rot as compared with the total fungal waste found in personally examined orange and grapefruit consignments in the four years 1957–60.

Table 1. COMPARISON OF THE INCIDENCE OF THE RED FRUIT ROT WITH THE TOTAL FUNGAL WASTE SEEN IN FRUIT CONSIGNMENTS IN THE YEARS 1957–60

	1957	1958	1959	1960
No. of citrus fruits examined	128,228	226,270	218,030	100,553
Total number of rots	7,304	5,997	4,420	601
No. of red rots	36	34	93	18
Percentage of red rots to total rots	0.5	0.6	2.1	3.0

In a single instance a reddish-brown fungus was isolated in culture as well as *P. italicum*. The former organism was identified by Mr. E. W. Mason of the Commonwealth Institute of Mycology, Kew, as *Ascochybe grovesii* Wells, an unusual type of Ascomycete which was diagnosed, classified and recognized as a new organism by Doreen E. Wells, and given its nomenclature as recently as 1954. The organism is of common occurrence on lumber wood, causing a brown surface stain.

Oranges inoculated with the *Ascochybe* fungus developed a very slow rot, in initial stages reddish-brown in colour but turning dark brown with age, and the fungus was readily isolated from the induced rot.

Uncertain as to whether the single isolate of the *Ascochybe* fungus was of chance occurrence or indeed primarily responsible for the dark red citrus fruit rot and later retarded by the development of the common blue mould fungus, the influence of diphenyl on the growth of both organisms on common nutrient agar media at different pH levels was studied, with the view of applying the knowledge gained to further attempts on the isolation of the causal organism of the new fruit rot.

Diphenyl, a fungistat much used in the citrus industry, proved to have little influence on the *Ascochybe* fungus. The rate of growth of the fungus was in some instances somewhat reduced, but the fungal fructifications—the hyaline conidia, the erect brown ascophores and hyaline ascospores—and the production of a characteristic reddish-brown diffusible pigment, remained unaffected by the diphenyl.

The response of the blue mould fungus *P. italicum* to diphenyl was most extraordinary. Instead of the normal fascicular development of a blue conidial mat on the culture media plates, growth was strikingly arrested, and very small atypical, well-raised, furrowed colonies developed changing in colour from whitish to yellow-bronze to reddish-bronze, often with a relatively wide dark red peripheral zone.

Conidia formation was generally inhibited, at times atypical with coarse stunted conidiophores bearing very few sterigmata and very few conidia. Most of the hyphal cells in the pigmented zone had reddish pigmented contents.

Oranges wounded and inoculated with *P. italicum* and placed with diphenyl under a bell-jar under dry and moist conditions developed the common blue mould rot, but with diphenyl in closed screw-capped jars the rot developed slowly and instead of the typical blue mould rot, irregularly scattered fascicular growths appeared, changing in colour in irregular patterns from dirty white to yellow-bronze to reddish-bronze, and blood red patches were also formed. Inoculated oranges without diphenyl in closed jars developed normal blue mould rot. In short, inoculated oranges with diphenyl in closed jars had produced, under the conditions of the experiment, a rot similar to some of the rot samples which showed visible reddish fungal growth on the fruit rind found in fruit consignments from Israel.

Whether the lack of oxygen or the increased ratio of carbon dioxide in the air mixture, and other substances as ammonia gas can induce the same type of rot is under investigation. It should be noted that two oranges in ammonia-treated experimental fruit consignments from Israel in 1958 actually showed the new type of red rot.

Fuller details will be published elsewhere.

I wish to express my gratitude to Mr. Marcus J. Sieff, director of Marks and Spencer, Ltd., and also to Mr. Nathan Goldenberg, chief of Marks and Spencer's Food Development Department, for generously placing at my disposal all laboratory facilities at Marks and Spencer's Analytical Laboratory.

Growth Requirements of Pome-Fruit Tissues

CORTICAL and pith tissue from apple fruitlets undergoing cell division and vascular tissue from more mature fruits have been grown in sterile culture¹. In this communication further definition of the growth requirements of apple and other pome-fruit tissues is made.

Growth of pear and quince fruit tissues in sterile culture was obtained on media similar to those used for apple tissue culture. Disks of tissue (thickness $\times$ diameter, 1 mm. $\times$ 3.8 mm.) excised from the mid-cortex of immature pear (Packham's Late, 45 days from fertilization, weight 20 gm.) and quince (Van Deman, 66 days from fertilization, weight 20 gm.) fruits showed no growth on a modified White's medium (agar content 0.55 per cent). Addition of coconut milk was without effect but addition of 2,4-dichlorophenoxyacetic acid (2 p.p.m., resulting medium termed A) induced active growth involving cell division. Addition of coconut milk to A (final concentration 10 per cent by volume) further stimulated growth. These responses to coconut milk and 2,4-dichlorophenoxyacetic acid resemble those obtained with apple fruitlet tissue excised during the period of cell division.

The effect of kinetin on the growth of these tissues has also been studied. Kinetin and *l*-asparagine, when both added to medium A, stimulated markedly the growth of pear cortical tissue, the stimulation exceed-

Fig. 1. Pear explants excised 45 days from fertilization after 34 days in culture. Right, explant which has shown negligible growth was cultured on medium F; left, on medium E

ing that of coconut milk. With quince cortex this stimulation was less marked, the response being less than that obtained with coconut milk. The influence of *l*-asparagine, kinetin and 2,4-dichlorophenoxyacetic acid on the growth of immature pear cortex is indicated in Table 1.

Table 1

Medium	Mean weight (mgm.) of explants after growth for 34 days
A (modified White's medium + 2,4-D 2 p.p.m.)	36
B (A + <i>l</i> -asparagine 180 p.p.m.)	67
C (A + <i>l</i> -asparagine - 2,4-D)	17
D (A + kinetin 0.1 p.p.m.)	46
E (A + <i>l</i> -asparagine + kinetin)	120
F (A + <i>l</i> -asparagine + kinetin - 2,4-D)	17

(LSD at 5 per cent level = 9, at 1 per cent = 12)

2,4-D = 2,4-dichlorophenoxyacetic acid.

Kinetin does not influence growth in the absence of 2,4-dichlorophenoxyacetic acid, stimulates only slightly in its presence, but stimulates appreciably in the presence of 2,4-dichlorophenoxyacetic acid + *l*-asparagine. Apple vascular tissue also responds to kinetin in the presence of 2,4-dichlorophenoxyacetic acid¹. The growth effects of kinetin on other cultured tissues have all been observed in the presence of indole-3-acetic acid².

The rates of growth of pear cortical tissue on medium E and of quince on medium A + coconut milk were several times greater than those of apple vascular and fruitlet tissue on either of these media. Cultured pear and quince tissue is composed of very small cells, and percentage growth increment expressed on a cell-number basis is usually greater than that expressed on a fresh-weight basis.

Attempts have also been made to culture tissue from relatively mature pear and quince fruits. Only slight proliferation was obtained from pear cortical explants excised 113 days after fertilization and cultured on medium A supplemented with coconut milk, but more active growth was obtained from quince (variety Missouri Mammoth) cortical tissue excised 90-154 days from fertilization. Both 2,4-dichlorophenoxyacetic acid and coconut milk were needed to induce this proliferation. No information is available about the length of the period of cell division in pear and quince fruits, but it might be expected to be of short duration as in the apple. Since picking time for quince is about 170 days from fertilization, it is likely that with this fruit growth has been obtained from cortical tissue after the cessation of

cell division. Explants from mid-cortex and pith of apple fruits of similar maturity showed negligible growth. Disks of tissue from relatively mature pear fruits excised so that a vascular bundle ran centrally through each explant showed more active growth than tissue from the cortex, medium *E* giving more rapid growth than medium *A* + coconut milk. Apple vascular tissue (variety Sturmer) requires both 2,4-dichlorophenoxyacetic acid or an equivalent and a cell-division stimulant (coconut milk or kinetin) for active growth in culture¹. 2,4-Dichlorophenoxyacetic acid or an equivalent is also essential for growth of pear vascular tissue, but this tissue is apparently much less dependent on a cell-division stimulant.

The possibility of replacing 2,4-dichlorophenoxyacetic acid by other compounds has been investigated. Apple and pear vascular tissue did not grow when 2,4-dichlorophenoxyacetic acid (1–5 p.p.m.) was replaced by indole-3-acetic acid (0.3–5 p.p.m.). Higher concentrations (30 p.p.m.) of indole-3-acetic acid produced some growth, but still considerably less than 2,4-dichlorophenoxyacetic acid. Potato-tuber tissue in the presence of coconut milk also shows this unusual dependence on 2,4-dichlorophenoxyacetic acid². Quince cortex was more responsive to indole-3-acetic acid which, although relatively ineffective at 5 p.p.m. with this tissue, at 30 p.p.m. was nearly as effective as 2,4-dichlorophenoxyacetic acid (5 p.p.m.). For the growth of apple and pear vascular and quince cortical tissue, 2,4-dichlorophenoxyacetic acid can be replaced by some related phenoxy acids (for example, 2,4,5-trichlorophenoxypropionic acid).

Tissue has also been cultured from other pome fruits, namely, medlar (*Mespilus germanica* L.), Japanese quince (*Chaenomeles superba* Rehd.) and oriental pear (*Pyrus calleryana* Decne.).

The work reported has been assisted by grants from the Rockefeller Foundation and from the New Zealand Apple and Pear Marketing Board. Thanks are expressed to Mrs. G. E. Mark and Miss D. A. Bridson for skilled assistance and to Dr. H. R. Thompson for statistical analyses.

Protoplasts from *Penicillium glaucum*

Bachmann and Bonner¹ were able to obtain free protoplasts from *Neurospora crassa*, if this fungus was cultivated in thick liquid media, such as 20 per cent sucrose and 10 per cent enzyme preparations. Protoplasts emerge through pores in the hyphal walls. The authors showed, by means of a microscopical photo-series, that the protoplasts regenerate to form a complete new fungus mycelium.

If *Penicillium glaucum* was cultivated on thickened serum it was also possible to form protoplasts. Cells of the fungus were inoculated in thickened guinea pig serum between two sterilized glass plates and the upper glass bordered and fastened with paraffin. After some time (7–14 days) those upper plates were loosened, dried and stained with a May-

Fig. 1. Formation of protoplasts from *Penicillium glaucum* in a medium of thickened cell-free guinea pig serum. ($\times$ c. 1,500)

Grünwald-Giemsa solution. (This simple method is very suitable for staining the internal structures of hyphae in microscopical preparations.) Fig. 1 shows the connexion of the protoplasts with the 'vacuoles' of the interior structures of the hyphae.

The photomicrograph shows reddish-grey, very tender forms between and on the blue hyphae. Some of these forms are in direct connexion with the pores and 'vacuoles' of the hyphae (a). Arrows b and c show these forms flowing out of the vacuoles.

In similar experiments with thick liquid media, such as sera and cell liquids, a wide extension of the hyphae was observed. Here the typical internal structures of broad hyphae found continues outside the hyphae. They are embedded in complexes, the finest structures of which seem to move slowly into the surrounding medium without producing definite contours. The same effect could be seen if *Penicillium glaucum* was embedded into living plants. This, together with some photomicrographs, is published elsewhere².

Other experiments have been carried out on soft forms of protoplasts³. These results concerning the extension of internal structures may help towards understanding the above phenomenon⁴.

In spite of the fact that these observations are different from the growth of fungi in normally used media, which regularly produce a quick and unrestricted growth, the present observed forms are unnatural. Under natural conditions there are many opportunities for fungi to move into living tissues or thick cell liquids and cause fermentation. Therefore it is necessary to pay attention to those alterations in the fungal elements, in order to prevent mistakes of diagnosis. Also for the sake of common biological examinations the study of changes of the cell elements, caused by alterations of the surroundings, is most important^{4,5}.

ENTOMOLOGY

Food of Housefly Larvæ

ALTHOUGH considerable information has been published on the nutritional requirements of fly larvæ (refs. 1-5 and Mer, G. G., personal communication) the actual natural food of these insects has never been unequivocally described. The biotopes of housefly larvæ consist of a variety of materials which by themselves appear nutritionally inadequate, but which have dense microbial floras (for example, animal excrements).

Culture methods for fly larvæ commonly used in laboratories require the addition of yeast to aqueous suspensions of either wheat bran, grass meal, oats or other similar materials². Silverman and Silverman³ replaced yeast by a controlled bacterial flora and achieved a more uniform growth of larvæ. In larvæ reared on this medium Mer (Mer, G. G., personal communication) found mainly bacterial cells in their foreguts. That living micro-organisms are not necessary for larval growth was shown by Greenberg⁴. He found that 'CSMA' medium containing an uncontrolled microbial flora could be used, after being autoclaved, for culturing *M. domestica* under sterile conditions.

The aim of the present experiments was to clarify the larval relationship to *Escherichia coli*, which is the dominant micro-organism in breeding sites of housefly larvæ.

Newly hatched larvæ of *Musca vicina* Macq. were reared aseptically⁵ for 3 days (to maximal body weight) at 35° C. at a density of one larva per gm. of experimental diets. These were mixtures of wheat bran (40 per cent), milk powder (2.5 per cent), and water (57.5 per cent) incubated for varied periods (Fig. 1) at 30° C. with approx. 4×10^4 *E. coli* (laboratory strain) per gram of medium, and autoclaved prior to use.

The results, which are summarized in Fig. 1, show that the wheat bran-milk suspension does not support larval growth when sterilized before substantial bacterial multiplication took place. This nutritional deficiency is, however, progressively

Fig. 1. Relationship between growth of *Musca* larvæ and concentration of *E. coli* in the wheat bran-milk mixture. Top line, number of *E. coli* per gm. of mixture. Bottom line, incubation period of mixture at 30° (hr.).

Table 1. THE EFFECT OF FEEDING DRIED CELLS OF *E. coli* TO HOUSEFLY LARVÆ. 35 NEWLY HATCHED LARVÆ WERE USED PER EXPERIMENT

Amount of desiccated <i>E. coli</i> in diet (gm.)	(per cent)	No. of larvæ surviving at 72 hr.	Average larval weight at age of 72 hr. (mgm.)	No. of larvæ pupating	No. of flies hatching
0.3	1.2	0	—	—	—
0.6	2.3	13	1.4	0	—
1.25	4.8	33	10.8	18	11

3.40	12.0	35	21.0	33	32
Wheat bran-milk mixture containing 7×10^8 <i>E. coli</i> /gm.					
		32	18.9	31	29
Synthetic diet*					
		28	14.8	23	21

* This consists of vitamin-free casein 2.5 gm., cholesterol 0.025 gm., ribonucleic acid 0.025 gm., salt mixture No. 2 0.016 gm., 'Nipagin' M 0.07 gm., powdered filter paper 8.0 gm., water 17.5 gm.; and the following vitamins (μ gm./gm. dry diet): thiamine 47, riboflavin 47, pyridoxine 38, pantothenic acid 95, nicotinic acid 238, folic acid 19, choline chloride 2,377, biotin 0.4, inositol 1,902, *p*-aminobenzoic acid 95, and vitamin B₁₂ 0.2.

compensated by the accumulation of *E. coli* cells in the initial mixture. Larval growth was optimal when the bacterial concentration had increased to 8×10^8 per gram of diet, which corresponds to an approximately 9.6 per cent weight increase over that of the deficient initial medium. On diets containing the above or higher concentrations of *E. coli*, rates of pupation and adult emergence were comparable to values obtained on stock culture or natural housefly media.

To determine whether the nutritional value of *E. coli* is due to its cellular constituents or products of its metabolic activity, Seitz filtrates of the *E. coli* diets, supplemented with cholesterol (0.1 per cent) and adjusted to the texture of the initial mixture by addition of powdered filter paper, were prepared. Since these diets failed to support larval growth, it is evident that *E. coli* cells contain essential nutrients.

Washed *E. coli* were desiccated to constant weight, and were afterwards mixed in graded amounts (see Table 1) with portions of 25.0 ml. of water and 8.0 gm. of powdered filter paper (particle size <10 mesh) which had been previously impregnated with 0.05 gm. of cholesterol⁵. The texture of the diets resulting after autoclaving was as loose as that of media incubated with living bacteria. Thirty-five newly hatched larvæ were grown aseptically for 3 days on each of these diets.

The results of a typical experiment are summarized in Table 1. The growth-rate of *Musca* larvæ is obviously proportional to the dietary level of the dried bacteria and becomes optimal at concentrations (9.1-12.0 per cent) which closely resemble the weight addition of *E. coli* cells required to 'complete' the wheat bran-milk mixture. This indicates that, apart from cholesterol and water, *E. coli* cells are the only food derived by the larvæ from the above media.

When compared with a synthetic diet, the nutritional superiority of *E. coli* diets is striking. It should be recalled that dried *E. coli* contain 75 per cent of a protein which has a notably higher nutritional value for rats, chicks⁶ and housefly larvæ¹ than conventional animal proteins. However, since cholesterol addition to the *E. coli* diet was indispensable for larval growth, the bacteria used appear to lack this constituent of animal cells.

One may conclude that the diverse materials on which housefly larvæ seem to thrive in Nature⁷ are

merely substrates for bacteria, and these are most likely to be the actual food of the larvæ. It might be worth considering the use of desiccated *E. coli* with the above-mentioned supplements as a medium for standardized housefly rearing.

This work was carried out at the Medical Research Laboratories of the Medical Corps, Israel Defence Forces, during 1957.

BACTERIOLOGY

Comaprison of Strains of *Streptomyces griseus* which produce Streptomycin and those which do not

WE have examined a streptomycin-producing strain of *Streptomyces griseus*¹ and two mutants derived from it which did not produce streptomycin. The two mutants arose by treatment with mustard nitrogen². They were isolated as a single colony by the method previously described³. Out of 1,387 *Streptomyces griseus* colonies grown from single spores after treatment with mustard nitrogen there appeared 33 non-producing colonies. Only two of them remained stable non-producers after being transferred several times. Their cultural and physiological characteristics differed from the parent strain.

After cultivation in media proposed by Waksman⁴ they behaved as different species.

Comparing our strains on various sources of carbon, they proved to have different characteristics. They all grew on 1 per cent maltose, dextrose, pectin, amylo soluble, glycogen, *d*-ribose, xylose, *d*-fructose, mannose, *d*-galactose, dextrose, *l*-arabitol, mannitol, glycerol, malate, succinate and fumarate, but did not grow, or very weakly so, on media containing 1 per cent saccharose, cellulose, inulin, rhamnose, sorbose, dulcitol, inositol, acetate, tartarate, formate, pyruvate. Pronounced differences have been revealed on media containing arabinose and citrate (Table 1). One of the non-producing strains (No. 45) which was isolated first was not able to grow on citrate as the sole source of carbon. The inability to grow on citrate, however, was not connected with streptomycin production because the other non-producing strain (No. 20/52) was able to use this substrate in the same way as the parent strain did. The inability to make use of citrate was not connected with decreased permeability towards citrate. All three strains were able to decompose citrate. Citrate disappeared from the medium and oxygen consumption, measured in a Warburg apparatus, increased. (Citrate disappearance

Table 1. CARBOHYDRATE UTILIZATION BY *Streptomyces griseus*

Carbon source	Parent strain <i>Streptomyces griseus</i>	Mutant strain No. 45	Mutant strain No. 20/52
Arabinose	+	++++	++++
Citrate	+++	+	+++

Inoculations were made by spore suspension on agar slopes, and results read on the fourteenth day of incubation.

was measured by chemical⁵ determination of citrate in the supernatant, and by measuring the carbon-14-citrate isotope activity in the supernatant.)

The parent strain and mutant 20/52 consumed citrate with a lag phase of about 1 hr.; the other mutant without any lag phase promptly oxidized citrate and increased its Q_{O_2} .

No metabolic block could occur in the two mutant strains in connexion with their inability to produce streptomycin, because both of them could synthesize their protoplasm from simple carbon sources and inorganic nitrogen sources.

There was, however, one striking difference between producing and non-producing mutant strains. The mutants in shaken culture grew only for a very short period of time. The young hyphae branched very early in their development in every direction and they soon were packed together into spherical clumps, characterized by an almost homogeneous centre and short hyphae protruding from it into the medium. These clumps grew in size, and spores were produced in very great numbers during the first 24 hr. of the culture. This mode of growth could be observed both in synthetic and complex organic media. It was not possible to achieve normal growth by changing the carbon-nitrogen ratio.

These results indicate that there exists some difference between streptomycin-producing and non-producing strains which lies in some fundamental metabolic change. Although the mutants were able to go through all important metabolic processes, they were not able to develop normally.

Metabolism of Small Bodies isolated from a Stable *Proteus* L Form

BACTERIAL *L* forms consist of morphological elements of various sizes and shapes¹. Many investigators of the *L* forms have paid special attention to granular bodies of a diameter of about 0.2 μ , which are very often found in *L* cultures. According to Tulasne, these granules, or some of them, are viable and represent an important stage in the life-cycle of the *L* form². This view has, however, been criticized by other workers^{1,3}.

Fig. 1. Electron micrograph of small bodies isolated from a culture of *Proteus* L9 by means of differential centrifugation

Separation of various morphological elements in an *L* culture by means of differential centrifugation has been described by Mandel *et al.*^{4,5}. This technique has been applied in the present work. A stable *L* strain (*L9*) derived from *Proteus vulgaris*⁶, was grown in a serum-free medium⁷ and subjected to centrifugations at 5,500–78,000*g*. Thus fractions were obtained which essentially consisted of granules having a diameter of 0.1–0.3 μ (Fig. 1).

The respiration of these granules, when suspended in the growth medium, was measured and compared with the respiration of the total culture. Table 1 gives the average values obtained from a number of experiments of this kind. It can be seen that the respiration of the small *L* granules is of the same order of magnitude as that of unfractionated *L* cultures. *L* bodies mechanically disintegrated for 5 min. in a Mickle disintegrator show at the most a very low respiration.

Table 1. AVERAGE VALUES OF RESPIRATION-RATES EXHIBITED BY *L* BODIES AS MEASURED BY THE WARBURG TECHNIQUE. THE *L* BODIES WERE SUSPENDED IN THE GROWTH MEDIUM

	Small granules	Total cultures	Total culture after mechanical disintegration
QO ₂	200	402	< 5

The change in the nucleic acid content of the granules and the incorporation of phosphorus-32 into these bodies during 2–4 hr. incubation in the growth medium were also studied. The nucleic acid content remained approximately constant or decreased somewhat. The incorporation of phosphorus-32 in the nucleic acid fraction of the granules (prepared by the Schneider procedure) corresponded to less than 0.2 per cent of the nucleic acid content of these bodies. Under similar conditions, the nucleic acid content of whole *Proteus* L9 cultures increased 2–3 times. Therefore, the possibility that the small amount of phosphorus-32 incorporated into the granular fraction could be attributed to contaminating *L* bodies of larger sizes cannot be excluded. Similarly, no significant incorporation of phosphorus-32 into the protein and lipid fractions of the small *L* granules could be ascertained.

The ribonucleic acid-content of the granules was found to be about the same (about 4 per cent) as that of unfractionated *L* bodies. The deoxyribonucleic acid content varied considerably and was often remarkably low (cf. Mandel *et al.*⁵).

The specific activities of the enzymes, succinic dehydrogenase and catalase, in the granules were

found to be comparable to those of *L* bodies present in unfractionated cultures.

The experiments which have been described indicate that, under the prevailing conditions, the biosynthetic capabilities of the *L* granules studied are at the most very low compared to unfractionated *L* cultures. The high respiratory power of the granules is, however, worth emphasizing. Mandel *et al.*⁴ reported that the small *L* bodies isolated by them from *Proteus* P18 cultures did not degrade glucose aerobically. In these experiments, however, the *L* granules were not suspended in the growth medium, but in a Krebs medium. We have found that neither fractionated nor unfractionated *Proteus* L9 bodies respire in the latter fluid.

The view has been presented that the granular elements found in *L* cultures represent protoplasmic debris². As shown in Table 1, however, mechanically disintegrated *Proteus* L9 bodies exhibit at the most a very low respiration. Thus, the granular bodies described above seem to be characterized by a higher structural organization than the dispersed protoplasm. The presence in the granules of succinic dehydrogenase, catalase and ribonucleic acid, in roughly similar amounts per mgm. dry weight as in *L* bodies not subjected to differential centrifugation, is also worth mentioning in this connexion.

GENETICS

Relation between X-Ray Sensitivity and Cell Stages in Males of *Drosophila melanogaster*

LÜNING¹ has shown that the rate of dominant lethals and gross rearrangements varies with the time from irradiation to insemination, with a peak around 7–10 days after the treatment. He suggests that the peak corresponds to irradiated spermatids which hence are supposed to be more sensitive than mature sperm. Auerbach² claims that the sensitive stage, although it may include late meiosis, consists mainly of spermatid stages. Khishin³, comparing the mutation pattern from irradiation of larvæ, pre-pupæ and pupæ, agrees with Auerbach. Fritz-Niggli⁴ adopted the same technique and deduced by analogy the following pattern of time-lapse between irradiated stages and insemination: mature sperm the 1st–4th day; spermatids the 4th–7th day; meiosis the 7th–10th day; and from the 10th day after irradiation spermatogonia.

The present investigation is an attempt to find the time of the appearance of the sperm irradiated in

meiosis by a direct method, and at the same time to correlate this with the sensitivity pattern. Mavor^{5,6} showed that irradiation of females caused primary nondisjunction. The same ought to be true also in males if meiotic stages are irradiated. The appearance of individuals in which the paternal sex-chromosomes both have entered the sperm cell will indicate that the cell had been treated before anaphase I. In the present experiment the occurrence of XO males has been used as an indication of genetical damage. At the same time the induction of nondisjunction between the X and Y chromosomes in the males has served as a criterion of early meiosis (prior to anaphase I).

The following stocks were used: the females were taken from a $y w sn \text{♀} \times y w sn$; $sc^s Y \text{♂}$ stock and the males from a $y^{16} \text{♀} \times y^{16}$; $sc^s Y \text{♂}$ stock. The normal offspring would be y females and $w sn$ males. Individuals which had lost the X and/or $sc^s Y$, and consequently were XO, would phenotypically be $y w sn$; and eggs fertilized by an X; $sc^s Y$ carrying sperm (nondisjunction) would give wild-type females due to the presence of the y^+ locus in the Y chromosome ($y w sn$; y^{16} ; $sc^s Y$). As these females also may arise through induced crossing-over between the X and the Y chromosome, each wild-type female was tested individually. The majority of these were due to nondisjunction. The males were picked out when 0-1 day old. They were either irradiated when they had woken up after treatment with ether or kept without females for 3 days prior to irradiation. The males were irradiated with a dose of 1,100 r. (2 min.). Immediately after irradiation the males were transferred to a mating box. The first mating period lasted 4 hr., but from the 4th day onwards each period consisted of 24 hr. Between the first mating period and the 4th day the males were kept with an excess of females.

Table 1. 0-1-DAY AND 3-4-DAY-OLD y^{16} ; $sc^s Y$ MALES WERE GIVEN 1,100 R. IN AIR AND WERE THEN MATED TO $y w sn$ FEMALES. TOTAL NUMBER OF OFFSPRING AS WELL AS RATE OF XO MALES AND WILD-TYPE FEMALES ARE GIVEN

Mating period after irradiation	0-1-day-old males			3-4-day-old males		
	Percentage XO ♂♂	Percentage wild type ♀♀	Total offspring	Percentage XO ♂♂	Percentage wild type ♀♀	Total offspring
0-4 hr.	0.46	0.01	20,538	0.32	0.03	44,635
Fourth day	0.33	0.03	62,692	0.20	0.04	43,016
Fifth day	0.75	0.03	50,552	0.43	0.02	38,766
Sixth day	1.33	0.01	24,735	0.61	0.02	17,571
Seventh day	2.21	0.22	18,100	1.24	0.12	14,155
Eighth day	3.47	0.51	13,350	1.55	0.21	11,706
Ninth day	2.39	0.19	7,772	0.96	0.13	8,724
Tenth day	0.54	0.18	27,946	0.49	0.14	8,312
Eleventh day	0.46	0.14	30,044	0.19	0.05	7,807

From Table 1, which shows the results after irradiation of 0-1-day- and 3-4-day-old males, it can be seen that, independent of the age of the males at time of irradiation, the number of induced XO males rises steeply from the 4th day, reaching a peak on the 8th day after treatment and then decreasing towards the 11th day. As regards the frequency of induced wild-type females, the rate is practically unchanged from the first mating period until the 6th day after irradiation. On the 7th day after irradiation there is a sharp increase in the frequency of wild-type females. The frequency reaches a peak during the 8th day after irradiation, followed by a drop towards the 11th day.

It is of special interest to compare the frequency of induced XO males and the rate of induced nondisjunction females during the 4th-10th day after irradiation. It can be seen that the peak of XO males coincides with the peak of nondisjunction females. Since the occurrence of nondisjunction females is used as the criterion of early meiosis (prior to anaphase I) there is an agreement between the highest X-ray sensitivity and cells treated at early meiotic stages.

About the same sensitivity pattern is obtained after irradiation of 0-1 and 3-4 day old males respectively. There exists, however, a discrepancy in the amplitude of the sensitivity. The frequency of induced XO males, as well as the rate of induced nondisjunction females, is much lower in the experiments with 3-4 day old males. This difference is statistically significant except for the first mating period. There is a fairly good agreement between these findings and Lünings¹ conclusions that 6-7-day-old males vary much less than 0-1-day-old males between different stages of spermiogenesis.

These experiments show that the treated meiotic cells become available for insemination during the 7th day after irradiation and onwards. From the present material it can be concluded that the peak of sensitivity presumably corresponds to cells treated during metaphase I or before anaphase I is completed. This conclusion is supported by sensitivity studies performed on different material⁷⁻¹⁰.

VIROLOGY

Virus Survival as a Seasonal Factor in Influenza and Poliomyelitis

THE pronounced seasonal fluctuations in the morbidity of influenza and poliomyelitis are largely unexplained. Both diseases can probably be transmitted by airborne infection and by many other ways which involve the survival of the causative virus in the dry state. For many organisms survival in air can be taken as indicator for survival in the dry state in general. Consequently it seemed worth while to study the influence of temperature and humidity on the survival of the viruses of influenza and poliomyelitis in air.

Earlier experiments with aerosols¹ of many organisms showed that—at least in the range of indoor temperature—the influence of temperature is small ($Q_{10} = 2-3$) compared with the influence of humidity. Furthermore it became evident that the relative humidity and not the absolute humidity is the determining factor.

Both viruses were aerosolized for 2 min. with an indirect spray (mean droplet diameter 6μ) into a

Fig. 1. Death-rates for influenza virus (O) and poliomyelitis virus (x) in air plotted against relative humidity

static system ($4 M^1$). Influenza virus (PR_8) was suspended in one part allantoic fluid and one part 2 per cent Difco peptone. Poliomyelitis virus (type 1 OSI) was suspended in one part Hanks salt solution with lactalbumin-hydrolysate and 5 per cent horse serum and one part peptone. At various times samples were taken for 2 min. with modified capillary impingers containing 1 per cent peptone or 1 per cent peptone with Dulbecco buffer.

Virus was titrated by amnion inoculation for influenza and by the plaque method on human amnion cells (strain U) for polio-virus.

From the logarithmic phase of the inactivation curves at various relative humidities, death-rate constants were calculated, using $K_s = \Delta \log N_0 / \Delta t$ (t denoting time in minutes). K is plotted against

relative humidity in Fig. 1. For influenza virus the death-rate is high (0.091 ± 0.024) at 50–90 per cent relative humidity and low (0.0073 ± 0.0031) in the range 15–40 per cent relative humidity. The transition is rather sharp. These results are mainly in accordance with the limited experiments published previously by other authors²⁻⁴. For poliomyelitis the inverse is true. Inactivation is slow ($K = 0.0089 \pm 0.0036$) at high relative humidity and very fast at low relative humidity. In fact, below 45 per cent no virus could be detected 30 sec. after spraying, which means that less than 0.03 per cent of the virus was left. The transition is again sharp.

In temperate climates influenza generally is a winter disease, occurring during the period when the relative humidity indoors is low as a result of heating. In Fig. 2 the seasonal variation of indoor humidity is plotted. The period of increasing influenza morbidity coincides with the period during which the survival of the virus in air is optimal.

Increase of poliomyelitis morbidity occurs during summer, that is, during the period when the indoor relative humidity is optimal for the survival of the virus in air (and presumably in the dry state in general).

Consequently the relative humidity, indoors, is considered as an important environmental factor contributing to the seasonal fluctuations of the morbidity of these two virus diseases.

Association of *Olpidium brassicae* and Tobacco Necrosis Virus

TOBACCO necrosis virus infects the roots of many plants, usually without symptoms. The virus is soil-borne¹⁻³, but the conditions necessary for natural infection have not been determined. Attempts to obtain artificial infection of roots by adding virus suspensions to roots of plants grown in sterilized soil commonly fail.

The relationship of *Olpidium brassicae* to tobacco necrosis virus infection was investigated because of claims⁴⁻⁷ of an association between tobacco necrosis virus and lettuce big vein disease, with which *O. brassicae* is invariably associated^{8,9}.

Further circumstantial evidence for the association of tobacco necrosis virus and *O. brassicae* was obtained in the present work by microscopic detection of *Olpidium* in the roots of *Cleome spinosa*, *Fragaria vesca*, *Chenopodium amaranticolor*, tobacco, and French bean infected with tobacco necrosis virus.

When suspensions of *Olpidium* zoospores from lettuce plants shown by root assay to be free of tobacco necrosis virus, and suspensions from macerated virus-infected cowpea leaves were simultaneously watered on to potted lettuce seedlings, much greater

Table 1. AVERAGE NUMBERS OF TOBACCO NECROSIS VIRUS LESIONS PER ASSAYED PLANT FROM INOCULATION OF LETTUCE ROOTS WITH *Olpidium brassicae* AND TOBACCO NECROSIS VIRUS

Treatment	Total number of plants assayed	Total number of plants infected with virus	Average number of virus lesions per plant assayed
<i>Olpidium</i> + virus	40	38	36.7
Virus only	31	17	0.7
<i>Olpidium</i> only	20	3	0.1*
Nil	14	1	0.1*

* Infection probably resulting from contamination.

root infection by tobacco necrosis virus occurred than when the virus alone was applied. Results in three experiments are summarized in Table 1.

Similar results were secured when cowpea, French bean, cabbage, cucumber, and tobacco were inoculated with *Olpidium* and tobacco necrosis virus. The results have been repeated in water culture in the laboratory with seedlings raised in Petri dishes.

The mode of action of *Olpidium* zoospore suspensions in thus increasing root infection with tobacco necrosis virus is not known. Conceivably, the fungus may act as a virus vector or it may predispose the roots to infection. Zoospore suspensions from lettuce roots infected with both *Olpidium* and tobacco necrosis virus have caused virus infection of roots even without added virus. As tobacco necrosis virus is released naturally by infected roots¹⁰, however, this does not necessarily mean that *Olpidium* is acting as a virus vector.

It is possible, but unlikely, that some factor other than *Olpidium* obtained from lettuce roots is responsible for the increased virus infection; a final decision on this must wait until it becomes possible to grow *Olpidium* in pure culture.

The advice of C. E. Yarwood and R. G. Grogan is gratefully acknowledged. C. E. Yarwood, N. W. Frazier, and T. Bowman kindly furnished plants naturally infected with tobacco necrosis virus.

AGRICULTURE

Contribution of Rainwater to the Nutrient Economy of Soil in Northern Nigeria

THE contribution of rainwater to the nutrient economy of soil in many regions of the world has been studied. At Samaru, Northern Nigeria, 80 litres of rainwater from eight rain gauges were collected in 1959. The water was concentrated by evaporation from dilute sulphuric acid and the concentrate analysed for all major nutrients except sulphur. Forty-two inches of rain fell during the 1959 season. The results are expressed in p.p.m. of each element

Table 1. NUTRIENT CONTRIBUTION OF RAINWATER IN 1959 AT SAMARU, NORTHERN NIGERIA

Nutrient	p.p.m.	lb./acre
Nitrogen		
Ammonium	5 000	47.6
Nitrate	0 230	1.2
Organic	0 125	2.0
Total	5 355	50.8
Phosphorus	0 555	2.3
Potassium	3 500	32.8
Calcium	0 100	0.9
Magnesium	0 110	2.60
Sodium	5 750	53.8

in the total composite sample, and have been converted to pounds per acre (Table 1). Sampling procedure excluded any measure of seasonal distribution.

So far as I am aware, the nitrogen, potassium and sodium figures are the highest recorded. Despite the high values, the sodium/potassium ratio is of the order found in New Zealand by Wilson¹. He has shown that the nutrients present in snow originate from the surface of the ocean where a large number of plankton, etc., in various stages of growth and decomposition are concentrated. These organisms narrow down the potassium/sodium ratio of the underlying sea. The potassium/sodium ratio of sea-water is 1:27, snow-water in New Zealand showed a ratio of 1:2.7 and at Samaru a ratio of 1:1.6 was found. The narrower ratio at Samaru may be due to a higher or different biological activity in the warm ocean around West Africa compared with New Zealand conditions. The low nitrate figure eliminates the possibility of large contributions from dust and electric storms. The lack of seasonal distribution figures makes the evaluation of the various factors impossible. Generally, the figures to date point to the ocean as the main source of rainwater nutrients, but do not exclude contributions from other factors.

The presence of such large and varied quantities of nutrients in the rainwater helps to explain several aspects of soil fertility in Northern Nigeria.

(1) Potassium fertilizers have never shown a positive response on annual crops of the region. Potassium from rainwater is probably adequate for crop growth, and the fertilizer potash aggravates what must be already an imbalance of potassium to other nutrients.

(2) Despite the lack of leguminous plants in bush fallows, build up of organic nitrogen is appreciable. From unpublished soil analysis data at Samaru, it has been calculated that an increase of 0.025–0.03 per cent total nitrogen can be expected over a period of five years. Rainwater, if not lost by run-off, would contribute 0.013 per cent nitrogen.

(3) Light sandy soils in the extreme north of the region show very low levels of total nutrients, and crop growth would seem to be impossible. The contribution of rainwater helps to explain the growth of crops on these soils.

These results indicate the importance of rainwater as a source of nutrients in the soil of Northern Nigeria. More detailed studies are in progress.

INSTITUTION OF THE RUBBER INDUSTRY (at the Café Royal, 68 Regent Street, London, W.1), at 6 p.m.—Mr. E. B. Storey: "Estimation of Wear Resistance of Tread Vulcanizates".

Tuesday, November 1

UNIVERSITY OF LONDON (at the Middlesex Hospital Medical School, Mortimer Street, London, W.1), at 5.15 p.m.—Prof. Hans Schaefer (University of Heidelberg): "Principles of Circulatory Regulation".*

INSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENT AND CONTROL SECTION (at Savoy Place, London, W.O.2), at 5.30 p.m.—Mr. G. G. Haigh: "Transistor Instrumentation in Rockets".

UNIVERSITY OF LONDON (at the Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. K. G. Denbigh: "The Science of Continuously Operating Systems" (Inaugural Lecture).

Wednesday, November 2

SOCIETY FOR ANALYTICAL CHEMISTRY (at the Wellcome Building, Euston Road, London, N.W.1), at 2 p.m.—Meeting on "Analysis of Semi-Conductors".

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Prof. R. H. S. Thompson: "Biochemistry of Multiple Sclerosis".*

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. M. J. Rickard: "The Stratigraphy and Structure of the Errigal Area, Co. Donegal"; Dr. B. A. Sturt: "The Geological Structure of the Area South of Loch Tummel".

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. J. Tubman and Mr. J. F. Manger: "Applied Petroleum Research on a Vehicle Dynamometer".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS AND COMMUNICATIONS SECTION (at Savoy Place, London, W.O.2), at 5.30 p.m.—Prof. W. J. G. Beynon: "The Ionosphere—a Review of Recent Progress".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5.30 p.m.—Dr. A. W. Brewer: "The Stratosphere".

INSTITUTION OF MECHANICAL ENGINEERS, INTERNAL COMBUSTION ENGINE GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Days of the Diesel Engine are Numbered".

BRITISH INSTITUTION OF RADIO ENGINEERS, RADAR GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—"Radar—Pulse or C.W.?" (a Discussion on Relative Merits).

SOCIETY FOR VISITING SCIENTISTS (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion Meeting on "Noise". Chairman: Sir Gordon Sutherland, F.R.S. Speakers: Mr. D. W. Robinson, Prof. W. Burns and Dr. A. Carpenter.

Thursday, November 3

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. A. M. Lwoff, For.Mem.R.S.: "Viral Functions" (The Leeuwenhoek Lecture).

MINERALOGICAL SOCIETY (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers (Anniversary Meeting).

UNIVERSITY OF LONDON (at Wye College, Wye, Ashford, Kent), at 5 p.m.—Dr. J. T. Martin: "The Plant Cuticle. Its Structure and Relation to Spaying Problems".*

UNIVERSITY OF LONDON (at the Middlesex Hospital Medical School, Mortimer Street, London, W.1), at 5.15 p.m.—Prof. Hans Schaefer (University of Heidelberg): "The Theory and Interpretation of the Electrocardiogram".*

INSTITUTION OF ELECTRICAL ENGINEERS (Joint meeting with the INSTITUTIONS OF CIVIL and of MECHANICAL ENGINEERS, at Savoy Place, London, W.O.2), at 5.30 p.m.—Dr. W. Abbott: "The Training of Overseas Graduate Engineers, with particular reference to the F.B.I. Scholarships Scheme".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. Charles Wilcocks: "Aspects of Medical Investigation in Africa—Schistosomiasis".* (Second of four Heath Clark Lectures. Further lectures on November 9 and 10.)

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. K. M. Rudall: "Regular Folds in Protein and Polysaccharide Chains".* (Fifth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

ARTHUR STANLEY EDDINGTON MEMORIAL TRUST (at Friends House, Euston Road, London, N.W.1), at 6 p.m.—Dr. William H. Thorpe, F.R.S.: "Biology, Psychology and Belief" (Fourteenth Eddington Memorial Lecture).

INSTITUTE OF METALS, LONDON LOCAL SECTION (at the Royal School of Mines, Prince Consort Road, London, S.W.7), at 7 p.m.—Dr. N. P. Allen, F.R.S.: "Long Term Creep Tests: a Discussion of Recently Expressed Views".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (Joint meeting with the BRUNEL COLLEGE OF TECHNOLOGY CHEMICAL SOCIETY, at the Brunel College of Technology, Woodlands Road, London, W.8), at 7 p.m.—Dr. O. C. Addison: "Non-aqueous Solvent Systems".

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Friday, November 4

MINERALOGICAL SOCIETY, CLAY MINERALS GROUP (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 10.45 a.m.—Autumn Meeting.

UNIVERSITY OF LONDON (at the Institute of Obstetrics and Gynaecology, Chelsea Hospital for Women, Dovehouse Street, London, S.W.8), at 3 p.m.—Prof. E. O. Amoroso: "The Endocrinology of Pregnancy".*

CIBA FOUNDATION FOR THE PROMOTION OF INTERNATIONAL CO-OPERATION IN MEDICAL AND CHEMICAL RESEARCH (at the Royal Institute of British Architects, 66 Portland Place, London, W.1), at 5 p.m.—Prof. J. Konorski (Warsaw): "Changing Concepts Concerning Physiological Mechanisms of Animal Motor Behaviour" (Twelfth (Annual) Ciba Foundation Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS, MEDICAL ELECTRONICS DISCUSSION GROUP (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Electro-Convulsive Therapy" opened by Dr. A. Spencer-Patterson and Mr. W. H. Stanton.

SOCIETY OF DYERS AND COLOURISTS, LONDON SECTION (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Mr. A. J. Lens: "Fastness of Dyes and Finishes".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. G. Porter: "Very Fast Chemical Reactions".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

EXPERIMENTAL OFFICER (at least 26, with a pass degree or equivalent, experience in radiochemistry and the use of normal beta counting equipment, and preferably a working knowledge of alpha and gamma counters), for work involving the measurement of radioactivity in biological materials—The Director, Agricultural Research Council, Biological Laboratory, Letcombe Regis, Wantage, Berks (November 2).

BIOCHEMIST (non-medical), for research on problems connected with tropical diseases—The Secretary, Hospital for Tropical Diseases, 4 St. Pancras Way, London, N.W.1 (November 5).

LABORATORY TECHNICIAN (qualified, with experience of laboratory work) at Brentwood Teacher Training College—Chief Education Officer (Ref. F.5.k), County Offices, Chelmsford (November 5).

RESEARCH ASSISTANT IN THE DEPARTMENT OF BOTANY, to carry out research with Dr. L. Powden on nitrogen metabolism—The Secretary, University College, Gower Street, London, W.C.1 (November 7).

HEAD (with high qualifications and experience) OF THE DEPARTMENT OF PHYSICS—The Bursar, College of Advanced Technology, Gosta Green, Birmingham 4 (November 8).

LECTURER (with medical qualifications registrable in this country) IN PSYCHIATRY—The Registrar, The University, Manchester 13 (November 12).

CHAIR OF PHYSICS in the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 15).

LECTURER or ASSISTANT LECTURER (with special qualifications in applied mathematics) IN THE DEPARTMENT OF MATHEMATICS of the Faculty of Science—The Registrar, The University, Manchester 13 (November 16).

EXPERIMENTAL AND THEORETICAL PHYSICISTS (with a first- or second-class honours degree in physics or mathematics), for research work in the Reactor Development Division—Personnel Branch (W.348/34), U.K.A.E.A., Atomic Energy Establishment, Winfrith, Dorchester, Dorset (November 17).

LECTURER (with a science degree with zoology as a major subject, followed by postgraduate experience leading to a higher degree and/or to published work) IN ZOOLOGY in the University College of Townsville, University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 86 Gordon Square, London, W.C.1 (Australia and London, November 19).

LECTURER (with a degree in science with honours in physics, some experience in the use of ionizing radiation, and preferably experience in using radioactive substances and in the principles of hospital or health physics) IN RADIATION PHYSICS AND RADIATION SAFETY OFFICER at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 86 Gordon Square, London, W.C.1 (Australia and London, November 19).

LECTURER or ASSISTANT LECTURER (with a special interest in plant physiology) IN BOTANY at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 30).

SENIOR LECTURER or LECTURER (with an honours degree or equivalent qualifications, and industrial and/or research experience) in **STRUCTURAL ENGINEERING**—The Registrar, Bristol College of Science and Technology, Ashley Down, Bristol 7 (December 8).

LECTURER in BIOCHEMISTRY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 86 Gordon Square, London, W.C.1 (Australia and London, December 5).

PLANT PHYSIOLOGIST (with a good honours degree in botany and research experience), for investigation of effects of temperature, oxygen and carbon dioxide on the respiration of apples—The Director, Ditton Laboratory, Agricultural Research Council, Larkfield, Maidstone, Kent (December 10).

SENIOR LECTURER in PHILOSOPHY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 86 Gordon Square, London, W.C.1 (Australia and London, December 10).

EMPIRE RHEUMATISM COUNCIL FELLOW (with medical or scientific qualifications), to prosecute research in the field of rheumatism—The General Secretary, Empire Rheumatism Council, Faraday House, 8/10 Charing Cross Road, London, W.C.2 (December 15).

AGRICULTURAL OFFICER (TOBACCO RESEARCH) (with a good honours degree in natural science (botany), or a degree in horticulture, with suitable postgraduate training or experience) in Nyasaland, for experimental work on tobacco including agronomy trials and plant breeding—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.68/4/04.

ASSISTANT, Grade B (with a university degree and preferably some teaching experience), to **TEACH BOTANY and ZOOLOGY** to Advanced Level students—The Clerk to the Governors, South-West Essex Technical College and School of Art, Forest Road, Walthamstow, London, E.17.

ASSISTANT PROFESSORS, INSTRUCTORS or LECTURERS (2) (with the degree of Ph.D.) in **PHYSICS**, to direct experimental research in low temperature or solid state physics—The Chairman, Department of Physics, Western Reserve University, Cleveland 6, Ohio, U.S.A.

CLAY MINERALOGIST (with an appropriate academic background and experience) in the **DEPARTMENT OF MINES and TECHNOLOGICAL SURVEYS**, Canada, for research aimed at the development of useful properties in Canadian clays and shales—Dept. MTS 1518, National Employment Service of Canada, 61 Green Street, London, W.1

GRADUATE RESEARCH ASSISTANT in the DEPARTMENT of PHYSICS, for a study of crystal structure and texture of materials by the techniques of electron diffraction and microscopy leading if desired to a higher degree—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1

LECTURER in the DEPARTMENT of PHYSICS—The Principal, Huddersfield College of Technology, Huddersfield

LECTURER (with marked ability at conducting and supervising research) in the **CHEMICAL PHYSICS of SOLIDS**—Prof. A. R. Ubbelohde, F.R.S., Department of Chemical Engineering and Chemical Technology, Imperial College of Science and Technology, London, S.W.7.

MASTER to TEACH PHYSICS (the post involves some Sixth Form work)—The Headmaster, King's College School, Wimbledon, London, S.W.10.

RESEARCH ASSOCIATE in ORGANIC CHEMISTRY, for work involving the isolation and identification of products formed by action of gamma radiation on organic compounds (mainly amines)—The Professor of Organic Chemistry, King's College (University of Durham), Newcastle upon Tyne 1.

RESEARCH FELLOWS and RESEARCH ASSISTANTS (4) in the DEPARTMENT of PHARMACY—The Registrar, Bradford Institute of Technology, Bradford 7.

SENIOR LECTURER or LECTURER (with a first- or second-class honours degree and a thorough grounding in electronics, and preferably experience in radar, telecommunications or radio guidance of missiles) in **ELECTRONICS** at the Royal Military College of Science, Shrivenham, Berkshire—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting D.600/0A.

TECHNICAL OFFICER (preferably with workshop and electronics experience), for research in muscle biophysics, using the electron microscope, X-ray diffraction, etc.—The Director, Medical Research Council Biophysics Research Unit, King's College, Strand, London, W.C.2.

PHYSICS OF THE SOLAR WIND

THE BALANCE OF BRITISH SCIENTIFIC EFFORT

THE thirteenth annual report of the Advisory Council on Scientific Policy, covering the year from July 1, 1959, to June 30, 1960, and the first to be submitted to Lord Hailsham as Minister for Science, is concerned with one main topic: the balance of scientific effort. There is also a brief but important discussion of the implications for scientific education of the Crowther Report; and a paragraph on space research states that, after reconsidering the subject, the Advisory Council reaffirms its previous advice that a programme of scientific research in space using satellites on a purely national basis would not, in itself, justify the very large expenditure necessary for a full-scale programme, including the development of a launching vehicle. This in itself is a particular aspect of the balance of our scientific effort, and that comment applies equally to the section of the report which contains the Council's observations on two particular fields of pure science, optical astronomy and seismology, which have become, for various reasons, neglected. In addition to the detailed results of the review of the Statistics Committee on Expenditure on research and development in the United Kingdom, 1958-59, there are appended, as usual, details of the numbers of graduate teachers of science and mathematics in schools and technical colleges, degrees and diplomas in science and technology, and estimated Government expenditure on civil research.

The review of the balance of our scientific effort follows the two earlier general surveys undertaken by the Council described in its reports for 1953-54 and 1956-57. In the first of these, the Council expressed the view that "a country's wealth and power are to-day largely determined by the extent of its scientific knowledge and its capacity to use that knowledge". In the second the Council found that the resources devoted to research and development for civil purposes were still far too small for Britain's needs. Government expenditure on civil research was then estimated at some £26.6 million. Excluding Treasury grants-in-aid to the universities and expenditure on civil research by the Ministry of Aviation and the Atomic Energy Authority, expenditure has since risen from an estimated £30.45 million in 1958-59 to £38.868 million in 1960-61, and these figures should be compared with the estimate of £300 million for the expenditure by British manufacturing industry on research and development given in the Department of Scientific and Industrial Research's report, "Industrial Research and Development Expenditure, 1958", published last April (see *Nature*, 186, 997; 1960).

The present review was undertaken at the request of the Minister for Science, who asked the Council for an authoritative review of the balance of scientific

effort in resources and man-power in the civil field, and in accepting this responsibility the Council has rightly attempted to define clearly both the aim and the limitations of any such review. It disclaims any attempt to seek a formal structure, but emphasizes rather the prime importance of devising criteria by which the points can be identified at which additional effort and resources will pay the greatest dividends. It is not concerned with administrative matters but with the strategy of scientific affairs, and suggests that it should be possible, on the basis of a comprehensive review, to indicate broad fields where further work is required, or where a new assessment or reorientation of effort seems desirable. It believes that the Research Councils and other government agencies operating in scientific and technological matters are the appropriate bodies to interpret its recommendations in terms of programmes of work.

In its reference to strategy it does not mean to imply that the advance of scientific knowledge can be directed: it uses the term in the sense in which it has been used by Sir Henry Tizard and Sir Hugh Beaver, for example, and again in the Barlow Report on scientific staff. Basic advances in science depend on the creative individual, or perhaps also on the creative minority, but from time to time obstacles can be removed, encouragement and resources provided for people who have ideas and the best use made of our limited resources. In other words, the Advisory Council is seeking to act on the policy that has long influenced and guided such bodies as the Nuffield Foundation and Rockefeller Foundation, and identify the growing points and ensure that they are adequately supported.

Clearly an official body, even if its functions are purely advisory, cannot commit public support with the freedom with which the private foundation can allocate resources, but there is no more encouraging feature of the present report than the way in which the Minister for Science and the Advisory Council itself take such a wide view of the Council's advisory function. If this is sustained, Britain will have at last one body responsible for considering how new scientific developments may interact among themselves and with the functions of existing institutions. There is a welcome note both of confidence and of authority about the present report which promises well for the future, and suggests that the Minister intends to use the Advisory Council as it could and should be used.

In the present survey the Advisory Council had some general problems much in mind. If advance is to be made with economy of effort, the growing points of knowledge require review from time to time to ensure that there is maximum contact and inter-

action between different fields of activity, and that the greatest range of professional skill is brought to bear on them. Paying particular attention to the frontiers of traditional disciplines, the Council notes the need to organize studies which cut across customary educational patterns or organizations, in order to attack a central or particularly resistant problem. The growing points in science are most frequently found in areas lying between the traditional disciplines and often involve the participation of several of them. The rigid separation of these disciplines can be awkward; but the solution of such problems is not necessarily to be found in the creation of new university departments and new disciplines. The research institute offers one solution, though the Advisory Council believes that universities should consider carefully the patterns which are emerging and encourage the effective interaction of the traditional skills.

Undoubtedly the expansion of universities and perhaps especially the establishment of new universities offer opportunities for flexibility and experiment, not so much in the new universities, which have first to prove themselves, as in the older universities. The colleges of technology, too, could play an important part, and the Council thinks that current schemes for training increasing numbers of scientists and technologists should not be planned without due regard to the changes which are taking place and to the fields where further effort is required. It had repeated evidence that it is very necessary for educational and professional structure to keep in step with the rapid evolution of science and technology.

The Council appreciates that its survey has important implications for economic and financial policy which strictly fall outside its purview. Its recommendations concern both subjects selected for their intrinsic scientific value or potentialities, and others chosen because of their importance for the British economy, or the conservation of its natural resources. No survey in the field of technology can ignore economic factors, and the review demonstrates once again how scientific and technical factors penetrate into every field of public policy and require evaluation along with other factors if sound decisions are to be made.

The review is based on a number of separate inquiries designed to present the widest body of evidence and of informed opinion about current scientific effort. The statistical basis is provided by a comprehensive survey carried out by the Council's Statistical Committee and already noted as appended to the report. Information and advice were also sought from the four Research Councils as well as the Royal Society, the principal professional institutions and Government departments mainly concerned with important aspects of applied science or technology. A list of such departments, public corporations, learned societies and institutions which is appended, however, shows some curious gaps among professional institutions, the names of the Royal In-

stitute of Chemistry, the Royal College of Surgeons and the Institute of Physics, for example, being absent, while it is also surprising that on the industrial side such bodies as the Federation of British Industries, the Association of British Chemical Manufacturers and the Society of Chemical Industry do not appear to have been consulted.

The result, nevertheless, appears to be a more comprehensive picture than was given in the Council's report for 1956-57, and the total expenditure of £480 million represents an increase in constant-value terms of about 40 per cent, or about 2.3 per cent of gross national product against 1.7 per cent in 1955-56. The pattern of cost of research in each sector, and to a lesser extent of sources of finance, remains broadly similar; but private industry is now financing 29 per cent of the total compared with 23 per cent previously, and the Government two-thirds instead of three-quarters. Non-defence expenditure has risen from £122 million to £243 million, and this expansion appears to be continuing. Estimates for the four Research Councils aggregate 37 per cent higher for 1960-61 than for 1958-59, but the table appended to the report shows a reduction in grants to learned and other scientific societies from £207,000 to £166,000 in 1960-61. Grants for overseas research increased from £1,735,000 in 1958-59 to £2,265,000 in 1960-61, and it should be noted that of a total Government expenditure on civil research of £30,453,000 in 1958-59 and £38,868,000 in 1960-61, £16,980,000 and £22,703,000, respectively, went to the Agricultural Research Council, the Medical Research Council, the Department of Scientific and Industrial Research and the Nature Conservancy.

Emphasizing that technological progress depends ultimately on the scientific work in the universities and technological institutions, the Advisory Council is once again concerned that British resources of highly qualified scientific man-power should be used as efficiently as possible in such institutions, and it believes that, to ensure this, further expenditure is required on improving equipment and facilities and in providing additional technicians. This may well be the more important with the further expansion of the universities and the establishment of new universities and colleges of technology, but it is also possible that the re-examination of teaching methods such as Prof. A. H. Cottrell and others have suggested could make a by no means negligible contribution to the efficient use of trained man-power. These are, of course, primarily matters for the universities and colleges themselves and for the professional institutions, and it is clear enough from the present report alone, and from what Lord Hailsham himself has said in the House of Lords, that the Advisory Council has no intention of endangering the autonomy of the universities. The present system of block grants for teaching and research through the University Grants Committee and of complementary earmarked grants for scientific research through the Research Councils appears to offer the minimum difficulties in administration and maximum freedom for the

universities; and the arrangements described in the Council's previous report for the periodic review and transfer of financial responsibilities for established research projects from the Research Councils to the University Grants Committee should make the system more effective.

Before discussing the survey in detail, the Council compares the United Kingdom expenditure on research and development in 1958 of £478 million, or 2.35 per cent of the gross national product, with the £3,971 million, or 2.74 per cent of the gross national product, expended in the United States. Whereas, however, in the United Kingdom the public sector accounts for 34.7 per cent of the cost of the work done, industry 57.1 per cent and the universities 4.8 per cent, in the United States the corresponding figures are 15.4, 75.3, 7.5 per cent, respectively. On the other hand, in the United Kingdom the public sector provides 68.5 per cent of the finance, industry 28.5 per cent and the universities 0.3 per cent, the corresponding figures for the United States being 61.0, 36.4 and 1.8 per cent, respectively. While the United States is devoting a somewhat larger proportion of its resources to research and development, it is probable that in both countries about 1.25 per cent of the gross national product is devoted to civil research and development work, and in this connexion the Advisory Council stresses the importance of using any opportunity which reductions in defence research and development may afford to increase the civil research effort in industry and elsewhere. It concludes further that a comparable scientific effort, in relation to the gross national production, with that of competitors should be maintained in Britain.

In regard to pure science, the Advisory Council's survey of the balance of effort leads it to the view that in pure mathematics Britain is losing ground, and that here the universities should give more attention to the provision of facilities for co-operative work. Oceanography and taxonomy have been relatively neglected, and in the section of the report which discusses the position of astronomy and seismology in some detail, the Council comments on the way in which British optical astronomy has lost considerable ground, partly in consequence of a low output of suitably trained specialists. Further steps are needed to bring astronomy to the notice of young physicists as a possible career, and while contemporary British resources in theoretical astronomy are substantial enough for an effective and relatively inexpensive contribution to British achievement and prestige, the proper deployment of these resources, which are scattered over a number of universities, is hampered by the lack of essential computing facilities. The provision of such large and expensive facilities may involve questions of university independence, and these are matters in which the universities may well be expected to take the initiative in co-operation, as in fact the Universities of Manchester and Liverpool have already done.

The Advisory Council endorses the recommendation of the British National Committee for Astronomy

that the first priority for British astronomical activity in the southern hemisphere should be an immediate development of the potential resources of the Radcliffe Observatory; but on radioastronomy it makes no comment on the Jodrell Bank position and is content to express the hope that the two techniques, which are not alternatives, but complementary in the exploration of space, will be developed concurrently. The British weakness in seismology is particularly stressed, and if Britain is to regain her position in seismological research and provide the minimum background for participation in any international scheme for the inspection and control of nuclear explosions, seismological centres must be developed at one or two universities. Specifically the Advisory Council recommends that the existing activity at the University of Cambridge be expanded to provide such a centre or unit, with appropriate equipment facilities for routine and specialized experimental and theoretical work and provision for university teaching, and that a similar centre be created in the University of Edinburgh.

These recommendations regarding astronomy and seismology arise out of the Council's special examination of these fields rather than out of the general survey. The latter, however, directed attention to some fields in medical science where further research effort is desirable, such as mental illness, dental disease and social and industrial aspects of medicine. Some of the less-popular technologies also offer fruitful opportunities, and particular reference is made to a serious deficiency over the whole field of civil engineering. Here the Council recognizes that educational developments offer a real opportunity for a serious examination of the possibility of greater co-operation in the use of facilities between the universities and colleges of technology and Government establishments, but it also points to a few major topics where further work is needed. The Council had much evidence that engineering prospects are intimately bound up with the economic production of new materials—conducting, semiconducting, insulating, magnetic and structural—and the improvement of existing ones, particularly materials capable of operating at much higher temperatures.

This is a field demanding much-improved collaboration between chemists, physicists, mathematicians and metallurgists both in universities and in industry, while research into energy sources and their utilization also involves difficult problems alike in co-operation and in assessing the balance of effort. The Council considers that research effort on the utilization of coal should be strengthened, particularly on the development of processes for the complete gasification of coal, and it has asked the Minister of Power and the University Grants Committee to consider ways of strengthening studies in coal technology at universities or colleges of technology. The need for further application in industry of refined techniques of calculation and automatic controls is also stressed, as are the needs for work on the measurement and suppression of noise, research into

the environmental conditions and other aspects of important livestock groups, the metabolic diseases of sheep and cattle, the storage of fruit, and research into industrial ceramics to provide management with control techniques of appropriate precision. Finally, it comments on the significant absence of basic research in the scientific assessment of such major problems as the conservation and long-term utilization of British water-supplies, the basis for policies of land utilization, and it urges that new measures may be required to deal with basic research relating to the conservation of our natural resources.

This is one of the points concerning which the Council recommends some change in the organization of research. While the survey indicates that the general pattern is in broad outline satisfactory, one important gap in responsibility is apparent. There is no clear general responsibility for the conservation of our natural resources, whether of minerals, water, land-use, biological resources or fisheries. The responsibilities of the Nature Conservancy, and of other Departments concerned, cover only limited aspects, and the Council believes that there may be justification for a Research Council with central responsibilities for ensuring that, over the whole, scientific knowledge and research are brought to bear on all these issues. The problem is being examined in detail by the Council's Biology and Allied Sciences Committee.

Another point relating to the organization of research arises out of the high cost of some research projects, and has already been noted in relation to both astronomy and seismology. The general point is frankly faced by the Council, and the report points out that the attempt to pursue certain types of scientific activity in many different universities can so disperse and dilute the British effort that in the end she achieves much less than could be expected from the total expenditure involved. This is quite apart from considerations of man-power, and even if the universities were fully supplied with technicians on the scale desirable to avoid waste of highly trained man-power to which the Advisory Council has previously directed attention, there is still the possibility that large installations of equipment, which must be serviced by many specialized technicians and which has a high obsolescence-rate, may distort the pattern of a university and lead to a situation in which the direction of its research may be determined not by the scientific stature of the men available but by equipment available.

The Advisory Council cites nuclear physics as an example of these dangers, and believes that less dispersal of the British effort in the early stages of its post-war development would have given a greater return for our expenditure in this field. The situation has since been recognized by the creation of the National Institute for Research in Nuclear Physics, and while the Council notes with satisfaction recent developments in the regionalization of electronic computers and proposals for joint operation of nuclear reactors, it suggests that extension of the idea of

such national institutes may require some adjustments of our scientific organization. Optical and radio astronomy, as well as space research, are other fields in which it is necessary to decide on the level of expenditure of resources and man-power that Britain is prepared to operate, and how dispersal of effort and unnecessary duplication of costly research facilities are best avoided. As alternative to a central institute available to workers in universities and similar institutions, it is suggested that such activities should be confined to one or two universities, as in fact it proposes for seismology.

The Advisory Council does not attempt to decide between these two alternatives, but it sees no other possibility if Britain is to participate effectively in such fields of research. Clearly the problem is one that should be engaging the active attention of the University Grants Committee as well as of the Research Councils; and the Advisory Council itself could well examine further the forms of organization and control appropriate to national institutes of this kind. Moreover, it may be necessary to extend the principle to the international plane, for in certain fields—the report instances space research, nuclear physics and oceanography—the point is fast being reached, if indeed it has not already been passed, at which international co-operation provides the only appropriate way of continuing effective work in these fields without subordinating the entire scientific effort of the United Kingdom to a few major programmes.

Finally, the Advisory Council observes that the problem is equally serious in industry. Fragmentation of the British industrial research effort can be a source of weakness, and of waste both in terms of money and of scientific man-power. Some degree of duplication in research may be desirable, and is indeed inevitable in the British economy with its multiplicity of independent industrial units; but it is notable that industrial leaders have of late been stressing the importance of co-operation in the attack on major problems of interest and importance to several industries. The Advisory Council points out further that there are to-day problems and projects of such magnitude in some fields that even large firms operating individually may only multiply, to no real purpose, research development and design work aimed at the same technical objectives.

No specific proposals are made for collaborative arrangements. The Advisory Council is content to remark that such co-ordination of effort is not merely essential but also possible and entirely compatible with a free economy. Without it Britain cannot hope to compete successfully in some of the newer fields of endeavour with other countries which are larger and wealthier, or which operate a political system in which industrial effort is co-ordinated centrally.

It may suffice here to note that the Advisory Council fully recognizes the bearing of education on the scale and effectiveness of the research effort, and that it welcomes many of the recommendations of the Crowther Report as likely to lead to education better suited to meet the scientific and technological

needs of Britain in the years ahead. This cogently argued and well-balanced report can only add to the stature and influence of the Advisory Council. It demonstrates that, in the Advisory Council for Scientific Policy, Britain now has a body capable of taking a comprehensive, balanced and authoritative view of the country's scientific effort, and assessing wisely the contributory factors. Its review shows clearly that there are still too many fallow fields and that there are also some fields in which activities could well become too large and distort the general pattern. The Council is clearly aware of the conditions which favour and encourage creative activity, and is concerned to do all that is possible to foster such conditions and to avoid any measures of adjusting the scientific effort which are detrimental to creative work. None the less, it does not hesitate where necessary to challenge the universities as well as industry, professional institutions and Government departments to the fresh thinking that may be required to shape existing arrangements or even institutions to new needs, and it is to be hoped that this sensible and balanced report will be closely studied by scientists and technologists and administrators whether in industry, in Government departments and public corporations, in research institutes or in universities and colleges of technology.

HISTORY AND PHILOSOPHY OF SCIENCE

Critical Problems in the History of Science
Proceedings of the Institute for the History of Science at the University of Wisconsin, September 1-11, 1957. Edited by Marshall Clagett. Pp. xiv + 555. (Madison, Wisconsin: University of Wisconsin Press, 1959.) 5 dollars.

THE conference reported in this volume is symptomatic of the great and accelerating attention given in the United States to the history and philosophy of science. The work of the earliest pioneers of these themes in that country, George Sarton, Chauncey Leake and Henry Sigerist, is bearing fruit in the establishment of many academic posts to which, alas, though not unnaturally, distinguished English exponents are being attracted as they observe through a second generation the lack of such posts in their own land. Sixteen papers besides invited commentaries were contributed to the conference.

In the opening paper, Prof. Rupert Hall, discussing the respective shares in the Scientific Revolution of the scholar and the craftsman, points out that during the seventeenth century the "medieval association of scientific activity with the universities was weakened though not disrupted" not only by the importance in science of men who were not academically trained but also by the shift of scientific activity from universities to the scientific societies and to circles basking in exalted patronage. Further interesting contributions on this theme are by Profs. Robert Merton and Francis Johnson, Dr. A. C. Crombie and Father J. T. Clark.

In a stimulating contribution on the "Role of Art in the Scientific Renaissance", Prof. Giorgio de Santillana shows how art and science joined in the crucially important theory of perspective evolved by the architect Brunelleschi (1377-1446). He notes that Brunelleschi was accepted by his peers as an intellectual, and in this context he shows the importance of the literary skill of Leon Battista Alberti (d. 1472).

Prof. E. J. Dijksterhuis gives a brilliant survey of the precursors of Newtonian mechanics. It is impossible to epitomize his amazingly clear account of the development of European mechanics before Newton, but this paper well repays careful study.

"Contra-Copernicus: a Critical Re-estimation of the Mathematical Planetary Theory of Ptolemy, Copernicus and Kepler", is by Prof. Derek Price. It is written with this writer's usual clarity and beautiful figures, with some abatement of the credit usually awarded to Copernicus.

A number of papers consider the influence on science of social and political developments in Europe. Prof. C. C. Gillispie has a learned discussion of the *Encyclopédie* and Jacobin philosophy. He considers that a certain arrogance on the part of French scientists was responsible for the movement to promote an unlearned "natural history" and for the forcible closure of the Paris Academy of Sciences. Dr. Pearce Williams finds some explanation of what he, following Prof. Guerlac, calls the anti-Newtonianism of the leaders of the French Revolution in the movement that he terms "Enlightened Stoicism". Reform was sought through moral regeneration. By 1792, Condorcet presented his scheme for universal education throughout France, based on a simplified science.

Prof. Thomas S. Kuhn considers the influence on the formulation of the doctrine of conservation of energy exercised by the discoveries of conservation in other kindred fields. Prof. I. B. Cohen gives a no less convincing and fascinating exposition of the discovery of the conservation of the electric charge. Prof. Carl B. Boyer emphasizes the importance of nineteenth century observation of chemical weight.

Turning to biology, Prof. J. W. Wilson suggests "Biology attains Maturity in the 19th century". Prof. J. C. Greene epitomizes the views and influence of Auguste Comte and Herbert Spencer. Prof. R. H. Shryock expresses the hope that biology has not yet reached maturity. Prof. Conway Zirkle maintains that there is no evidence that either Darwin or Wallace was influenced by Victorian political or economic *laissez-faire* or belief in the benefits of competition.

Prof. C. S. Smith describes "The Development of Ideas on the Structure of Metals". His paper, although technical, is beautifully lucid. He discusses the influence on metallurgy of the revival of interest in atomic theory. Dr. Marie Boas gives an interesting account of "Structure of Matter and Chemical Theory in the 17th and 18th centuries".

Into this galaxy of fascinating information and reflexion are inserted valuable papers recording pioneer experience in teaching the history and philosophy of science. Prof. Dorothy Stimson records the consistent success of such studies with the students at Goucher College; Prof. Henry Guerlac relates that engineering students at Cornell have been equally enthusiastic; Prof. Bernard Cohen gives a cheering historical sketch of the teaching of the history of

science at Harvard over a period of sixty-eight years; Dr. Boas follows with an account of her happy experience in giving courses open to all upper-class university students in an Arts and Science School.

Prof. Guerlac gives an eloquent and convincing exposition of the function of the study of the history and philosophy of science in promoting true education.

It should be added that exceptionally full bibliographies are attached to all the papers. Space permits no adequate account of the important material packed into this volume. Both the conference and the publication were sponsored financially by the National Science Foundation of the United States and by the Research Committee of the University of Wisconsin.

DOBOTHEA WALEY SINGER

ELECTRICAL CHARACTERISTICS OF THE EARTH'S STRATA

Overvoltage Research and Geophysical Applications
 Edited by James R. Wait. (International Series of Monographs on Earth Sciences, Vol. 4.) Pp. viii + 158. (London and New York: Pergamon Press, 1959.) 55s. net.

MEASUREMENTS of the electrical characteristics of the Earth's strata indicate the existence of several interrelated phenomena, which have been discussed from time to time in the literature. One of the effects is the potential which can be observed between two non-polarizable electrodes immersed in a porous medium, after the interruption of an applied step function current. This induced potential has a considerable bearing on the transient and frequency response of the medium. However, the phenomenon has, with a few exceptions, received scant attention.

The monograph edited by J. R. Wait consists of a collection of papers on the various aspects of induced potential. Various hypotheses for the occurrence of the normal effect observable in all naturally occurring porous media are fully discussed, and results of experimental work designed to test these hypotheses are given.

The emphasis of the majority of the papers is given to the geophysical application of the abnormal overvoltage effect observed in a porous medium containing electrically conducting particles, that is, metallic ores.

Theories of the transient and frequency response characteristics of such media are suggested, and the results of both laboratory and field investigations are given and discussed in relation to the suggested theoretical treatments. A short but useful paper on the field equipment required for prospecting for metallic ore bodies by the overvoltage method is included.

Some of the hypotheses advanced and indeed some of the practical results reported do not altogether agree with other published data on the subject. These differences are, however, mainly in degree rather than in fundamental concept. There appears to be, for example, some discrepancy between the discussion of the variation of measured conductivity of porous media with frequency, when this is compared with earlier reports. This discrepancy may be real and, in fact, represent a difference in the

response obtained from porous media with and without conducting particles.

The authors have given factual reports of the results of a concerted attack on the problem of the overvoltage phenomenon and its practical application to geophysical prospecting. The individual papers are well presented and the various discussions are logical and thought-provoking. The collection is well worth study by all research geophysicists, and should be read by anyone concerned with the flow of electrical current through Earth strata.

P. THREADGOLD

NATURAL PRODUCTS

Konstitution und Vorkommen der organischen Pflanzenstoffe (exclusive Alkaloide)

Von Dr. Walter Karrer. (Lehrbücher und Monographien aus dem Gebiete der exakten Wissenschaften. Chemische Reihe, Band 12.) Pp. 1207. (Basel und Stuttgart: Birkhäuser Verlag, 1958.) 136 Swiss francs; 136 D.M.

NATURALLY occurring organic compounds have fascinated chemists for very many years. Their interest began with substances possessing some easily recognizable property, such as colour, smell, bitterness, or toxicity, but to-day it ranges through the whole spectrum of natural products. In spite of this interest and the current rapid developments in an understanding of the biogenesis of such compounds, there has been no up-to-date dictionary of natural products. Although monographs are available for some limited groups such as carbohydrates, alkaloids, steroids and carotenoids, in the case of many groups, or even individual compounds, the collection of comprehensive information has entailed a long and tedious literature search. Dr. Walter Karrer has now eased this difficulty to a considerable extent. He has collected together details of organic compounds of known, or apparently known, structure found in plants, other than alkaloids. Even with these limitations about 2,700 natural products are described, ranging from hydrocarbons through depsides, carotenoids and terpenes to nitriles, pyrimidines and nucleotides.

The structural formula of each compound is given, as well as details of its distribution in the plant world. Key references to the elucidation of structure and synthesis are also listed. The information given about those groups of compounds with which I am familiar is accurate and comprehensive, the literature being covered to 1956, and the author is to be congratulated on the immense task which he has successfully undertaken.

For those concerned with structural elucidation of natural products, with their pharmacological activity, or with the biosynthesis of organic compounds, the appearance of this volume emphasizes the need for an even more complete dictionary of all natural products. Many compounds have been isolated which are inadequately described in the literature or the structure of which is still unknown. Often the same compound is described under different names. If some chemist would collect together the information about these compounds with the same thoroughness that Dr. Karrer has shown in the present volume, he would perform an invaluable service.

T. G. HALSALL

MOLECULES IN CRYSTALS*

By DR. DOROTHY HODGKIN, F.R.S.

Chemical Crystallography Laboratory, Oxford

ON this occasion, I wish to describe the structures, as we see them to-day, of a number of very remarkable crystals. These would certainly have interested the early Fellows of the Royal Society and particularly perhaps Hooke and Boyle, both of whom carried out experiments on growing crystals, observed the shapes of their faces and speculated on the arrangement of corpuscles within them. In his "Micrographia", in 1664, Hooke drew pictures of alum crystals side by side with sheets of globular bodies in hexagonal and cubic arrays (Fig. 1) and commented: "I think, had I time and opportunity, I could make probable, that all these regular Figures that are so conspicuously *various* and *curious* . . . arise onely from three or four several positions or postures of Globular particles, and those the most plain, obvious and necessary conjunctions of such figur'd particles that are possible . . . by these kinds of texture or position of globular bodies, may you find out all the variety of regular shapes into which the smooth surfaces of *Alum* are form'd . . . nor does it hold in superficies but in solidity also, for it's obvious that a fourth *Globule* laid upon the third in this texture, composes a regular Tetrahedron, which is a very usual Figure of the *Crystals of Alum*".

Boyle imagined the integral parts of a body might have a variety of shapes, not only globular. Among the Qualifications that conduce to Fixity, he imagined would be "the ineptitude of the component corpuscles for avolation by means of their branchedness, irregular figures, crookedness or other inconvenient shape, which intangles the particles among one another and makes them difficult to be extricated".

The structure of alum is considerably more complicated than Hooke's drawings propose. As we know it now, it is based on a series of studies made by Cork, Beavers and Lipson, using X-rays, and most recently, by Bacon and Gardner, using neutron diffraction. Each unit cell contains 4 aluminium ions, 4 potassium ions, 48 water molecules, 8 sulphate ions. Remarkably enough, the relative positions of the positive ions in the crystal conform with Hooke's suggestions. But the intermolecular attractive forces which hold the units together are clearly more complicated than simple close packing. Around each trivalent ion are 6 water molecules, in a regular octahedron, each exactly oriented with the hydrogen atoms directed symmetrically away from the metal ion: and the metal to oxygen distance here is relatively short—1.94 Å. Around the monovalent ions, the six water molecules have a more open, irregular arrangement with oxygen-potassium 2.97 Å.; and between the oxygen atoms of the water molecules and sulphate ions various short contacts can be traced, the shortest being those where one hydrogen atom lies in the direct line between the two oxygen atoms. The whole atomic

Fig. 1. Drawing from Hooke's "Micrographia" showing alum crystals and close-packed spheres. (A, B, C, D, Fig. 2 is an illustration to another section of the book)

arrangement is seen to result from a delicate balancing of a number of interlocking chemical and physical and geometrical requirements.

The knowledge we have of the exact arrangement of the atoms in this and many other crystals has been obtained as a direct result of the discovery of X-ray diffraction of crystals by von Laue, Friedrich and Knipping, and its development as a tool for structure analysis by W. H. and W. L. Bragg nearly fifty years ago. It is particularly sad that Prof. von Laue died only some months ago—but also a particular pleasure to think that he must have known before his death of the latest and most spectacular results of his discovery—results with which Sir Lawrence Bragg has been almost as intimately associated as he was in the first solution of any crystal structure.

The impression that I wish to give is one almost of direct sight of the atoms in crystals, an impression which has followed particularly from the use of Fourier series in interpreting the diffraction effects. In 1915, W. H. Bragg pointed out that the periodic

* Substance of a Royal Society Tercentenary Lecture delivered on July 23.

variation of the medium in crystals could be analysed by Fourier's method into a series of harmonic terms, the existence of which was indicated by the series of spectra obtained by diffraction from a given set of crystal planes. The recombination of the observed harmonic terms in a Fourier synthesis is now usually carried out mathematically to provide a physical measurement of whatever periodic structure is responsible for the observed diffraction effect—the electron density, if X-rays are used, potential distribution in electron diffraction, nuclear scattering power in neutron diffraction. The formulae involved may be given in the form

$$\rho_{xyz} = \frac{1}{V} \sum_{hkl} \sum_{\infty} \sum_{\infty} |F_{hkl}| \cos(\theta - \alpha_{hkl}) \quad (1)$$

$$\text{where } \theta = 2\pi(hx + ky + lz)$$

$$F^2_{hkl} = \left[\sum_n f_n \cos \theta_n \right]^2 + \left[\sum_n f_n \sin \theta_n \right]^2 \quad (2)$$

$$\tan \alpha_{hkl} = \frac{\sum_n f_n \sin \theta_n}{\sum_n f_n \cos \theta_n} \quad (3)$$

Here the first equation shows that ρ , the electron density in the case of X-ray scattering, can be found at a position xyz in the crystal cell by summing a series of which the coefficients of the terms $|F_{hkl}|$ are given by the measured intensities of the diffracted spectra. Both these intensities and the phase-angles α associated with them depend on the actual positions of the atoms in the crystal, as shown in the equations 2 and 3; while the intensities of the spectra may be directly measured on photographic films or by counters, the determination of the phase-angles presents more serious problems. Usually they are found through a series of approximations to the exact atomic distribution often involving trial structures and a variety of calculations, many of them also based on Fourier series; for example, F^2 series and series in which the phase-angles are calculated on some parts only of the structure, often with the coefficients modified by the subtraction of certain calculated atomic contributions.

The X-ray analysis of the alums happens to occupy a rather special place in the history of the crystallographic use of Fourier methods. In their investigation, it was first pointed out that by the study of an isomorphous series of crystals the phases as well as the amplitudes could be experimentally determined, and a direct picture of the atomic arrangement formed by Fourier synthesis without preliminary trial calculations. In the alums, the scattering power of the atoms can be changed by chemical substitution, for example, aluminium may be replaced by chromium, potassium by ammonium, rubidium, caesium or thallium, sulphur by selenium; and a direct calculation of the one-dimensional electron density distribution between two planes in alum crystals was first made by Cork in 1927. The crystallographic situation here is very simple since the alum crystal structure is centro-symmetrical. But the formal equations are clearly soluble for the three-dimensional asymmetric case, given three or more isomorphous crystals, as has been effectively demonstrated in the solution of the most complicated crystals so far analysed.

Fig. 2. Electron density in the plane of the benzene ring. Contour interval, $0.25e/\text{\AA}^3$ (from Cox, Cruickshank and Smith, *Proc. Roy. Soc., A*, 247, 1; 1958)

It has become common in the past few years with the advent of electronic computers to calculate the electron density in crystals in three dimensions. With simple crystals, these calculations can provide a highly exact picture both of the positions and of the modes of vibration of the atoms in the crystal. The analysis of benzene at -3° by Cox, Cruickshank and Smith may be quoted as an example. The electron density in the plane of the benzene ring (Fig. 2) shows rather distorted peaks over the carbon atoms. If the density to be expected from spherical carbon atoms is subtracted from this pattern, we get difference peaks which show the positions of the hydrogen atoms and also indicate atomic movements—that the molecule, as a whole, is oscillating with a root mean square amplitude of approximately 7.9° about the six-fold axis. Such a large amplitude of oscillation is permitted by the non-directed character of the intermolecular forces and cog-wheel packing of the molecules in the crystal. In diketopiperazine crystals the situation is rather different. The molecules are hydrogen-bonded together in bands in the crystal; the atomic positions are very accurately defined to within $0.004 \text{ \AA}$. through the X-ray analyses of Corey, Degeill and Marsh and electron diffraction studies by Vainstein. In the latest electron density maps calculated with data obtained with molybdenum $K\alpha$ X-radiation, the atomic maxima appear very sharp (Fig. 3). The contour interval is 8 times that on the benzene map, and the thermal parameters derived for each atom have been analysed by Dame Kathleen Lonsdale. It appears that in this crystal the chains of molecules linked by hydrogen bonds are behaving like bundles of sinuous and somewhat elastic ribbons. The easy movements are those by which the atoms move out of the plane of the ribbon, either by a translational or librational movement of the molecule as a whole. Translation of the molecule within the chain is slightly more difficult, and there seems very little oscillation about the normal to the ring system: by contrast with benzene, the root mean square amplitude of oscillation is here only 1.7° .

Once allowance has been made for thermal motion in interpreting electron-density maps, the deviations of the peaks from spherical symmetry seem extremely

Fig. 3. Above, electron density in the plane of the ring in diketopiperazine. The contour interval is $2e/\text{\AA}^3$ beginning with the 1-electron contour. Below, a composite drawing of the electron density over the hydrogen atoms. The contours are at intervals of $0.25e/\text{\AA}^3$ (from Degen and Marsh, *Acta Cryst.*, 12, 1007; 1959).

small: more accurate work at varying temperatures is required before these deviations can be taken very seriously as evidence of different varieties of chemical linking. Still, at the level of good approximate structure analysis, many interesting observations have been made. Some of these illustrate the ways in which molecules are restricted in their atomic arrangement, the flatness of aromatic or multiple-bonded systems, the staggered conformation of carbon chains, the tendency to form hydrogen bonds in certain preferred directions in relation with hydroxyl, amino and carbonyl groups. In oleic acid crystals, for example, Abrahamsson and Nahrngbauer find long V-shaped molecules, with planar double bonds and staggered chains, associated through carboxyl groups. In *i*-erythritol—analysed by Powell and Bekoe—small compact molecules, with hydroxyl groups on each of four carbon atoms, are knit together by two systems of hydrogen bonds in a complex tetragonal arrangement. In hexagonal crystals, the molecules of the amino-acid, cystine, have a spiral arrangement about a six-fold screw axis—identity requires a lattice repeat interval of $56 \text{\AA}$. There are close hydrogen-bonded contacts between amino and carboxyl groups within one layer, the layers being linked by S-S bridges. Observations on crystals such as these provide a solid basis of facts in the light of which we can interpret data from more complex molecules.

The electron-density patterns obtained from these crystals are mostly derived by a series of approximations based on trial structures. These approximations are easier to interpret if one or two atoms in the molecule are relatively considerably heavier than the others. The heavy atom positions can then usually be found unambiguously and their scattering contributions used to initiate a series of approximate electron density calculations. The effects have been exploited in a large number of recent analyses aimed at the determination of the actual chemical structure of natural products, sterols, terpenes and alkaloids, a variety of molecules with fantastic names and fantastic condensed ring systems, calycanthine, limonin, isoclovene, mirestrol—many others. Limonin, examined by J. M. Robertson and his students very recently, was effectively analysed twice over in the same crystal, since the derivative used, epilimonol iodoacetate, crystallizes with two non-crystallographically identical molecules per asymmetric unit. The character of the analysis may be illustrated by a half-way stage such as the third calculated three-dimensional electron density distribution (Fig. 4).

Here heavy peaks indicate atomic positions recognized earlier and used in calculating phase angles, small ones show newly appearing atomic sites—the relatively unknown are differently distributed in the two molecules. Both the detailed molecular structure revealed and the fitting of the molecules in the crystal make one astonished at the variety of complications present—differently sized and shaped ring systems and side-chains. An earlier example of a similar analysis—which grew out of Bernal's first attack on the sterol structures—is that of calciferol which, in the form of the iodonitrobenzoate, also has a very intricate crystal structure. Both these illustrate remarkably well the difficulties of crystal growing and melting which Boyle envisaged in relation to the "branchedness" of the building units.

Considered simply as an aid to X-ray analysis, heavy atoms seem to work best at a level at which

Fig. 4. Electron density contours taken from the third three-dimensional distribution calculated for epilimonol iodoacetate (after Arnott, Davie, Robertson, Sim and Watson, *Experientia*, 16, 51; 1960).

Fig. 5. Atomic positions in wet vitamin B_{12} crystals projected along a . The molecules in one layer are shown, together with a single molecule and the phosphate groups of molecules in the second layer. Small circles mark probable water molecule positions; dotted lines mark hydrogen bonds

their scattering power is roughly equal to that of all the other atoms present—for example, one bromine atom to about 24 carbon atoms, one iodine atom to 56 carbon atoms and so on—remembering that the scattering contribution is roughly proportional to the square of the atomic number. But much smaller relative differences can be exploited, as in the determination of the structure of vitamin B_{12} , where the heaviest atom, cobalt, contributes only one-tenth of the total scattering effect. Here the finding even of the exact molecular formula, $C_{63}H_{88}O_{14}N_{14}P\text{Co}$, depended on the gradual sorting of the atomic positions from various approximate electron density maps until it became clear which atoms belonged to the vitamin molecule itself, which to the surrounding water of crystallization. The knowledge from parallel chemical research that a benziminazole, sugar and phosphate group were parts of the molecule, greatly assisted the sorting process. But their relative positions in the molecule and the whole of the structure of the porphyrin-like nucleus followed from the X-ray analysis alone.

The vitamin B_{12} molecule proves to be quite compact, organized around the two planes of the inner porphyrin-like nucleus and the benziminazole group. Its geometrical form can be illustrated by a calculated projection of all of the atomic positions on the plane passing through the cobalt atom and four inner nitrogen atoms of the nucleus. From this projection it is clear that the benziminazole ring lies across the nucleus in a position mainly determined by packing considerations; it is also tilted about 10° from the direct normal to the projection plane and the nucleus is a little buckled where the two rings make contact. The different amide side-chains lead off from the nucleus in generally staggered arrangements; small deviations from these appear to be due to conflict with the requirements of intermolecular contacts, particularly through hydrogen bonds.

In outline the crystal structure is simple (Fig. 5). The roughly spherical molecules are arranged in approximately hexagonally close-packed layers, the two layers in each crystal unit being slid a little distance from the formal positions required by close-

packing, with the spaces between the layers occupied by water molecules. But in detail, the atomic arrangement is very intricate, a consequence of the exact molecular geometry. In wet B_{12} , where the crystals are suspended in their mother liquor, the acetamide and propionamide groups all make direct intermolecular hydrogen-bonded contacts—the B_{12} molecules are in contact with one another on every side. Between them, the water molecules, approximately 22 per B_{12} molecule, make additional hydrogen bonds with the active groups, particularly with the amide and phosphate groups and with one another. Along particular lines in the crystal structure, water is continuous from one side of the crystal to another and is probably trickling through it during X-ray photography in narrow streams, one molecule deep. As Sir Francis Simon suspected when he examined a model of the structure, the atomic arrangement is not the same in every unit cell throughout the crystal and, as the crystals are picked out of their mother liquor, a somewhat irregular transformation occurs. A few water molecules leave every unit cell, the B_{12} molecules slightly change their relative positions, two amide groups swing round carbon-carbon bonds and check the flow of water and there results a new, more imperfect but still largely crystalline molecular arrangement. The electron density calculated throughout the water molecule region in the air-

Fig. 7. Electron density in diketopiperazine calculated with reflexions limited at different spacings

dried crystals illustrates different degrees of order within the crystal pattern. Some water molecules, such as those hydrogen bonded to the phosphate oxygen atoms, are represented by high peaks; others by low ridges which seem to represent no more than the regions in which moving water molecules have been stranded in different unit cells as the crystals dry.

The atomic positions in the electron density maps for B_{12} , though distinct, are not so well defined as those shown earlier—a consequence of the smaller number of observable X-ray reflexions (spacing limit, 1.1 Å.) which in turn may be due to irregularities in the crystal introduced by the moving water molecules (Fig. 6). As the spacing limit is still further reduced the electron density pattern becomes increasingly blurred—the appearance of diketopiperazine in Fig. 7, calculated with different numbers of X-ray reflexions, shows the effect very clearly. The first drawing corresponds with the limit of reflexions observed for B_{12} , the second and third to limits of 1.5 and 2.0 Å. respectively, the fourth to 6 Å. At the fourth all individual atomic definition has disappeared. But at the third, although the pattern is much blurred, it is easy to recognize the molecule provided one knows approximately what to look for.

Diketopiperazine as an example of atomic definition, and these particular cut-off limitations on our view of atomic positions, have been chosen to illustrate our evidence on the structure of the protein crystals, myoglobin and haemoglobin. The molecules here are twelve to fifty times as large as B_{12} and composed of amino-acid residues linked in peptide chains. Many earlier lines of evidence indicated that within these molecules the peptide chain must be composed into a structure that had itself something of the character of a crystal lattice. Lindström-Lang described in imagination a protein molecule as itself a small crystal, in equilibrium with the surrounding medium,

with the peptide chains within it knitted together by forces well known from macrocrystals—van der Waals' forces and hydrogen bonds. It was Astbury who recognized that X-ray diffraction effects from many proteins suggested the chains were present in a specifically folded form, the α -fold for which Pauling, Branson and Corey proposed in 1951 a particular chain configuration, the α helix, following the long series of exact peptide structure X-ray analyses which began with diketopiperazine. To-day it is possible to see within myoglobin crystals the peptide chain and its configuration—indeed to visualize the positions of some 1,200 atoms as well as the 8 which occur in Fig. 7c; while in haemoglobin the peptide chain is as clearly outlined as the molecule as a whole is defined in Fig. 7d. This result has been reached through the very remarkable series of researches of Perutz, Kendrew, and their collaborators at Cambridge, who have exploited certain features of protein crystals to make a whole series of accurately isomorphous crystal structures.

Protein crystals were early observed occurring naturally in plant and animal tissues; one of the first described in the literature was the haemoglobin of the earthworm (Hünefeldt 1840), which crystallizes spontaneously in blood left to dry on slides. Early too, in the middle of the nineteenth century, one of the important properties of these crystals was recognized by Schimper—that they contain large volumes of water of crystallization penetrable by ions and by quite large molecules such as organic dyes without apparent disturbance of the crystal lattice. This property can be used to introduce heavy atoms into the crystal in order to make isomorphous derivatives of the proteins for X-ray analysis. The first such heavy atom isomorphously introduced, mercury in sodium *p*-chloromercury benzoate, was chemically attached by the SH groups in haemoglobin: others have been found to enter and lodge in definite positions in the crystal lattice by crystallizing the proteins in the presence of heavy atom-containing ions or molecules and by soaking them in appropriately buffered dilute solutions of the reagents. The molecules which have been shown to lodge in haemoglobin and myoglobin are a varied collection—*p*-chloromercury benzene sulphonate, mercuridi-ammine and aurichloride derivatives, *p*-iodonitrosobenzene, which reacts with the iron atom in the haem group of myoglobin, among others. Measurements of the intensities of some 10,000 X-ray reflexions from each of five different myoglobin derivatives and of several hundred reflexions for six different haemoglobin crystals have been made; and with the F_{hkl} values derived for these the full potentialities of equations (1) (2) and (3) have been exploited to derive phase angles and calculate directly in three dimensions the electron density in crystals of sperm whale myoglobin and horse met-haemoglobin.

So far, two three-dimensional electron density distributions have been calculated for the sperm-whale myoglobin crystals. The first of these, at 6 Å. resolution, shows the main back-bone structure of the molecule, a series of rod-shaped units linked together by strands of density and surrounding a rather heavy maximum, clearly the iron atom of the haem group. At 2 Å. resolution the rods and strands break up and, to an astonishing degree, the calculated density pattern defines the whole of the atomic distribution in myoglobin (Fig. 8a). One can see,

Fig. 8. Electron density calculated at 2 Å. resolution for myoglobin. The contour intervals are at $10 \cdot 32e/\text{\AA}^3$ with the first contour dotted, the electron density contours being drawn on sheets stacked together. *a*, To the right, one is looking down an α -helix, clearly marked by the concentration of density around a hole of low density; *b*, the model tilted to show the heme group on edge

Fig. 9. Electron density contours defining a tryptophan residue in myoglobin. Contours at $1/5\sigma/\text{\AA}^3$.

within each rod-shaped unit, the peptide chain wound in precisely the configuration required in a right-handed α -helix; there are in all eight distinct stretches of α -helix of very varying numbers of residues—one 24, one 19, one 18, two 16, one 8, two 7 residues long. These lie generally at considerable angles to one another and are linked either directly or by small stretches of open chain—one, two, three or more residues long. Projecting from the main chains are the different amino-acid side-chains and these too are surprisingly recognizable—the very flat aromatic units, phenylalanine and tryptophan (Fig. 9), for example, are easily distinguished from branched valine or extended staggered leucine; a terminal atom turning back towards the peptide backbone or to an isolated peak—a water molecule—as if to form a hydrogen bond helps to identify hydroxyl groups as in serine or threonine. Nearly the whole of the sequence of 153 amino-acid residue in the molecule can be traced—and much of it has already been checked with parallel chemical studies of Edmondson. The h  m group itself is very clear (Fig. 8b). On one side of it there is a single peak, probably a water molecule, attached to the iron atom in the same way as the water molecules to the chromium or aluminium ion in the alums. On the other side is a histidine group, corresponding with the benzimidazole group in vitamin B_{12} —and like it arranged with its plane at a general angle, about 10° , to the nearest Fe-N bond.

There are main chains—as suspected earlier—lying on either side of the h  m group and from these project other residues, mainly aromatic, tyrosine, phenylalanine, proline, and one other histidine residue. The molecules make contact with one another on every side in the crystal, directly and through water molecule bridges; they enclose channels through which smaller molecules and ions can move—carrying the heavy atoms with them. The spaces between and within them look ragged to one's eye. But clearly to approaching reactants they must offer specific attractions. So far as one can see, most of the heavy atom-containing molecules introduced are not chemically attached to

particular residues but individually trapped in clefts of various shapes and sizes within and between the molecules.

While in each small region of the myoglobin crystal one can see operating the same stereochemical conditions that determine atomic arrangement in smaller crystals, it is much more difficult to recognize the principles that determine the pattern of chain fitting into the molecule as a whole. Yet principles there must be, complex as the pattern is. With small variations and at low resolution only, similar patterns have been observed both in seal myoglobin and horse meth  moglobin. The crystal structure of h  moglobin is particularly interesting. Piecing together the low ridges of electron density observed in the three-dimensional electron density distribution, Perutz has found that each molecule is composed of four myoglobin-like molecules, packed together in an irregular tetrahedron. One might compare the packing here with Hooke's four globules were it not for the precise and intricate way in which chain locks into chain in the molecule as a whole. The iron atoms in the four h  m groups are found to be between 25 and 35 $\text{\AA}$. apart. Already one can see detailed chemical implications of the structure. While their situation in clefts between chains provides a ready explanation for the slow reaction that has been observed of the iron atoms with bulky reactants, they seem to be rather far apart for any direct interaction. Possibly changes in the rate constants as oxygen is added arise from a general loosening of the molecule as reaction proceeds.

At this point it would be possible to discuss the building up of units of the size of h  moglobin into still more complex molecules and crystals such as can be seen among the viruses. Poliomyelitis virus, for example, has been crystallized and gives very beautiful X-ray photographs. From these, Dr. Klug has deduced that the virus molecule is spherical and has an arrangement of sub-units over its surface which approximates to cubic symmetry. One of the formally possible arrangements seems very likely from the look of the electron microscope pictures. Others, still more complicated, have been found for other viruses.

In each of these enormous molecules there must be, at an atomic level, the same kind of intricate fitting together of individual atoms observed in simpler systems; and this leads us back to ask more intimate questions about the way in which the different molecules react with their surroundings. What, for example, is there in the chemistry of cobalt and iron that makes them specifically suitable for the biological reactions of vitamin B_{12} and h  m? In other fields of chemistry, new and most curious types of compound have been discovered, involving both cobalt and iron in hitherto unsuspected types of binding. The versatility of the chemical elements in their relations with one another is proving to be much greater than was supposed even a few years ago.

Looking back through history, one finds oneself impressed by the many characteristics of the molecular structures here described which were correctly inferred or imagined in the past, often from very indirect evidence. Yet these structures, as we have found them to be in detail, also contain new and surprising and undreamed-of features. The impact of the exact knowledge we now have is tremendous. It changes our whole outlook.

THE MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY

THE new buildings of the Manchester Literary and Philosophical Society in George Street, Manchester, were formally opened by Sir Cyril Hinshelwood, president of the Royal Society, on September 12 in the presence of the Lord Mayor of Manchester, who brought civic greetings and good wishes for the new venture. Prof. H. Lipson, president of the Society, who presided, referred to the past of the Society, which was indeed founded in 1781; but its premises with its irreplaceable library and records were destroyed by bombing in December 1940. He then commented that, although the Society now has its own building again, no society can live on its past. The membership of about 350 is little greater than in the time of Dalton and Joule, and Prof. Lipson hoped it would now increase and be maintained. The Society has a part to play in the life of Manchester that the University itself cannot hope to do.

Sir Cyril Hinshelwood, who had stoutly vindicated the function of the scientific society or academy in the conditions of to-day in his tercentenary address to the Royal Society, did not pursue that theme on this occasion; but, picking out the title of the Society and its original objective, "the advancement of literature and science", proceeded to discuss the arts and the sciences and, as he put it, to "roam destructively about, hacking at some of the useless conventional hedges which divide up liberal studies". It would appear, he began, that the division between the much-discussed 'Two Cultures' is not recognized in the Society, and the refusal to do so should be applauded and upheld: the dichotomy in question is largely illusory, but the illusion, in so far as it is believed or acted on, can do great mischief. So too can the false dichotomy between pure and applied science, and Sir Cyril suggested that it would be more sensible if people who took an intelligent interest in any of these things considered rather what they have in common than matters of difference. Inquiring further, Sir Cyril suggested that the philosopher, in the widest possible sense of the word, seeks some coherent vision of the world, something deemed worth while in its own right and worth the cultivation of skill and the exercise of effort to obtain. This, with the satisfaction of an urge to create, covers a large part of the liberal or philosophical or educated approach to existence, and the manifold ways in which it can find expression are only variations on the fundamental themes. The real antithesis to the liberal attitude lies in such things as the pursuit of power for its own sake, the accumulation of wealth except as a means to an end, or the basing of moral judgments on self-righteousness and prejudice.

Rejecting the view that the sciences deal with things and the arts with people, Sir Cyril insisted that both science and art are concerned with life, with living; the barriers between them are artificial, and in each alike there is a place for observation and experiment, for imagination and creative powers. Scientific

imagination does not differ from any other kind and is called into play in science at least as often as elsewhere. Nor is the æsthetic element without an important role in science, though less commonly recognized, and to try to draw a distinction between the natural sciences and some of the arts in terms of objectivity can be equally misleading. Science is more than the simple enumeration of the facts of Nature: it is the ordering of these facts into patterns which are felt to be significant and satisfying, which can be interpreted and explained, and both involve subjective judgments. The acceptance or non-acceptance of a physical principle as a fundamental law of Nature must in the end rest largely on an æsthetic judgment.

Even in abstract art, Sir Cyril thought the analogy and affinity with pure mathematics are suggestive, nor did he think curiosity and the excitement of discovery operate differently or to different degrees in the arts and in the sciences. It is the weakest kind of sentimentality to make enjoyment of poetic images dependent on some desperate determination to accept them literally or to shun all other knowledge. Passing over the problems raised by history, whether it is a science or simply the register of the crimes, follies and misfortunes of mankind and its strivings and virtues, Sir Cyril commented that history does not teach us much about the handling of men. The sympathy and imagination needed to understand motives and feelings, the wisdom and experience to judge effect are generated not by the study of history but by the processes of real life. The real value of history, like that of science, is the ordering of complex arrays of facts into patterns to give a coherent though never wholly objective view of the world, and in both, as in art, the exercise of a strenuous and disciplined technique is essential.

Before considering technology, Sir Cyril made the comment in passing that there is no greater mistake, in science or in the fine arts, than to under-value manual craftsmanship, and in some respects the educational system of Britain seems designed to divert some with potentially first-rate manual skill into being second- or third-rate mental workers. At every stage of their development, fundamental science and technology have been interdependent. To-day no technological institute can dispense with the best theoretical equipment; but no laboratory devoted to pure science can hope to advance far without the finest technological assistance, and governments, industries and universities have still to find the best solution of the problems of organization which this situation presents. Moreover, many of the fundamental laws of physics confront us with metaphysical problems such as the nature of space and time, of causality and determinism, about which it is easy for one untrained in philosophical thought to make very unwise statements. Conversely, the philosopher who deals with these matters is in grave danger of spinning words in a vacuum, if not of perpetrating blunders, if he does so without know-

Fig. 1. New meeting house of the Manchester Literary and Philosophical Society

ledge of what physics has revealed. Biology, too, needs an occasional injection of philosophy and in the last resort physicists, philosophers, biologists, psychologists and even moralists ignore one another at their cost when confronted with some of the deepest problems of existence.

Finally, concluded Sir Cyril, the liberal arts and sciences have in common that they seek a coherent vision of the world, and that they all demand a highly disciplined technique. They are not inherently superior or inferior to one another, and the actual content of a particular study has little influence on the development of personality. Only real experience of the world exerts such influence, and it is the liberal approach rather than the choice itself that matters. Sir Cyril qualified this declaration of independence—to follow one's own bent and to respect others who follow theirs—by urging that arts and sciences should be cultivated side by side. They are allies, not rivals or antagonists; and he rejected the idea that the pressure of modern life and the demands of specialization make it impossible for the scientist to know something of literature and the arts man to know something of science. What matters in the end is the atmosphere, the attitude and the approach. The right ethos is likely to be found, he said, in the Manchester Literary and Philosophical Society, and he hoped it would be maintained and spread far and wide.

After a vote of thanks to Sir Cyril moved by Lord Simon of Wythenshawe, and conferment of honorary membership on Sir Cyril, the building was opened for inspection, and members of the Society may justly feel that the dignity and spaciousness which the architects, Messrs. Francis Jones and Sons of Manchester, have brought to their new home admirably fit it for the function which Sir Cyril commended. Besides the main lecture theatre on the ground floor, seating about 200, in which the opening meeting was held, with comfortable seating, good acoustics, and all the devices needed by a contemporary lecturer, it has on the first floor a smaller lecture theatre for more informal meetings of about 70, which can be arranged for social meetings also, and the Dalton Room, opening off which is the members' common room. The Dalton Room, which also serves as the council room, houses a small reference library and a collection of relics, mementoes and books relating to the history of the Society and its members, while the periodicals and other publications received from all over the world will be available in the common room, where light refreshments will be served. Although the Dalton Room holds pride of place, the whole building is light and appropriate to its contemporary purposes, and the equipment and furnishings are in keeping. Great credit is reflected on all responsible for the detailed planning and its execution.

OBITUARIES

Prof. F. J. M. Stratton, O.B.E., F.R.S.

A GREAT many friends all over the world will have learned with regret of the death on September 2 of F. J. M. Stratton; 'Professor' to some, 'Colonel' to others, 'Chubby' to many.

Frederick John Marrian Stratton was born in Birmingham on October 16, 1881. He was educated at King Edward's Grammar School, at Mason University College (afterwards University of Birmingham) and at Gonville and Caius College, Cambridge. He was third Wrangler in 1904, Isaac Newton Student in 1905, and Smith's Prizeman in 1906. In the years before 1914 he was a mathematics lecturer at Caius College and also assistant director of the Solar Physics Observatory, Cambridge, under H. F. Newall. His early papers covered a wide range of astronomy, including celestial mechanics, but the appearance of Nova Geminorum (1912) focused his attention on what proved to be a problem of life-long interest. In 1914 he had gone to the Crimea with Newall, intending to observe the total solar eclipse of August 21, but on the outbreak of war he hurried back to England and joined the Army immediately. He served with great distinction in France and was awarded the D.S.O. and the Légion d'Honneur.

The First World War was the first of the great upheavals of this century and the one for which the world was least prepared. At its end, Stratton returned to Caius College, as senior tutor, to face what was a difficult time of readjustment for the University at Cambridge, as much as for Britain as a whole. If one may judge by the remarks of his pupils it was a job for which his personality and experience admirably suited him, and which he carried out with much success. During this period he continued to give lectures on astronomy, among them one of the first general courses on astrophysics to be given in Britain. Somehow he also found time to go to Sumatra for the 1926 total solar eclipse, where with C. R. Davidson he made successful observations of the chromospheric spectrum.

On Newall's retirement in 1928, Stratton was appointed professor of astrophysics and director of the Solar Physics Observatory, relinquishing his tutorship at Caius. He held this post until 1947, although his tenure was interrupted, first by a serious illness in 1931 and later much more extensively by the Second World War. This period of his life was notable for the encouragement and help he gave to a whole generation of younger astronomers, many of whom still remember him with gratitude. He organized three more eclipse expeditions, to Siam, Canada and Japan, but was dogged by bad luck with the weather. Only in Japan, in 1936, were results of any scientific value possible. Even then the success was only partial, the Sun being covered by a cloud almost at the instant of second contact. However, members of his team made good measurements of wave-lengths in the spectrum from very near the Sun's limb, and obtained chromospheric spectrograms, study of which by Thackeray and by Woolley stimulated a good deal of later work.

In 1934, Nova Herculis appeared and, despite the inadequate equipment of the Solar Physics Observa-

tory at Cambridge, Stratton and his staff during the next few months obtained a remarkable record of the spectrum changes of what turned out to be an extremely interesting star. Work on this spectrum absorbed much of his energies for several years, culminating in the production, with W. H. Manning, of the "Atlas of the Spectrum of Nova Herculis", using material made available from all over the world. This is still one of the most complete records we have of a nova outburst.

In 1939, at the outbreak of war, Stratton was bitterly disappointed at the refusal of the British Army to allow him to undertake active service again (at the age of fifty-seven), but nothing would stand in the way of his giving service of some kind. So the war years found him travelling extensively, in Canada, Australia, India and elsewhere, on duties for the Royal Corps of Signals. At the conclusion of the War, he had only two more years as professor of astrophysics, and in the conditions then prevailing in England, he realized he could do little to get back into active astronomy. He did, however, complete an interesting history of the Cambridge Observatories up to 1947. After his retirement he was deputy scientific adviser to the Army Council for two years and continued to serve on innumerable committees.

To celebrate his seventieth birthday, some of his pupils undertook, with Dr. A. Beer as editor, to produce what was to have been a *Festschrift*, but which expanded, as more and more of his friends came to hear of it, into two thick volumes, "Vistas in Astronomy". Indeed, the publication quite outgrew its original purpose, no doubt causing Stratton some amusement as well as gratification, and a third volume appeared, while yet others are still in preparation.

Stratton's official posts formed only a part of his activities. During 1925-35 he was general secretary of the International Astronomical Union, and did much to foster what was one of the earliest and most successful of the international scientific unions. He was also general secretary of the International Council of Scientific Unions from 1937 until 1952, and general secretary of the British Association, 1930-35. He was president of the Royal Astronomical Society, 1933-35, and its foreign secretary during 1945-55. He was honorary secretary of the Society for Visiting Scientists during 1948-55. He was president of Caius College, 1946-48, and at the time of his death was its senior Fellow. He served as president of the Society for Psychical Research, 1953-55. He was a life-long supporter of the Unitarian Church and was ever active on behalf of ex-servicemen's societies and causes. In the early 1930's he gave much help to refugee scientists from Central Europe. He was elected to the Royal Society in 1947.

Until his last years, Stratton lived life at the double. He thought fast, talked fast, decided fast, and in his younger days moved fast. Despite great sociableness and much hospitality, he was not an easy man to get to know really well, in part because he tended to keep his life in watertight compartments. He made great contributions to science and learning, chiefly by help and encouragement to younger men,

and not merely in Great Britain alone. A bachelor, he was completely devoted to his College, his pupils, to astronomy and especially to the International Astronomical Union, to his comrades of the First World War, and to his duty wherever he thought it to lie. Personal convenience, comfort or profit came very low indeed on his scale of priorities. He was one of the most generous men I have ever met, and one of the most modest. Astronomer, soldier, don, Unitarian, internationalist, he has left the world greatly in his debt.

R. O. REDMAN

AMONG young intellectuals in the universities, in the years before the First World War, it was commonly regarded as a sign of feebleness of intellect to believe that war was conceivably possible; and indeed as a mark of moral obliquity to take any personal steps to meet such an emergency. Fortunately a substantial minority, in reality no less intelligent, paid rather little attention to the intellectual and moral stigma; and the following short story of a small group of them at Cambridge describes one of the earliest contributions of young scientific men to national preparedness for war.

In 1908, under the Haldane Scheme for the Territorial Army, the Officers Training Corps of the Universities took the place of the earlier Volunteers. In Cambridge, in addition to the previous battalion of infantry, units were established of cavalry, artillery, engineers and medicals. Two years later, under the imaginative leadership of F. J. M. Stratton, a Signal Company was started and before long a wireless telegraph section was formed as part of it. Encouraged by Bertram Hopkinson, professor of engineering, who lent a room in his laboratory, the wireless section began work on the design of sets for field work and it drew in a remarkable group (as it proved) of young scientists for the task. It was not possible in those days to go and buy components from dealers, and radio valves did not exist. Everything had to be built up in workshop, laboratory, or tent, by members of the section itself. Since sets had to be portable, a generator was designed to be fitted to a bicycle, and during 'operations' a member of the section pedalled steadily, if wearily, to provide power for transmission. When communication failed, for example, between Farnborough Common and Eelmore Hill, it was re-established by flag and/or bicycle.

A photograph exists showing the ten members of the section in 1912, together with Captain Stratton commanding the Signal Company and a portable radio set complete with antenna. In it, among others, are Lance Corporal Henry Thirkill, Lance Corporal T. L. Eckersley, Private Harold Spencer Jones and Second Lieutenant A. V. Hill. Those were early days. By 1914 the wireless section had expanded considerably, and since no reserve of regular W/T officers existed when the War broke out, it was natural that members of the section should be drawn into field wireless. In fact, the section provided senior wireless officers for four armies. After the War, the Signal Company was more generously treated by the War Office, and a special research group was formed inside the wireless section.

Prof. (alias Lieut.-Colonel) Stratton recalled that, among the members of his Signal Company, the following could be counted: several who went into industry, one of whom was scientific adviser to Marconi's for twenty-seven years; four vice-chancellors and five masters of Cambridge colleges; nine

professors; nine Fellows of the Royal Society and three Nobel Laureates; one director of scientific research, Admiralty; one chief engineer of posts and telegraphs, India; one secretary of the World Meteorological Organization; three successive secretaries-general of the International Council of Scientific Unions; one Astronomer Royal; two major-generals; [one D.S.O.]; one bishop; one Colonial chief justice; one M.P.; and one Olympic gold medallist. This list, as its author admitted, was rather a fraud, since on the average each person in it occurred twice. Nevertheless, it is rather impressive, particularly when one remembers that two-thirds of these people served in the Signal Company during its initial years 1910-14.

A. V. HILL

Dr. J. Brooks, O.B.E.

DR. JACK BROOKS, principal scientific officer at the Low Temperature Research Station, who died in Cambridge on October 2, was in charge of the work on eggs and poultry.

Brooks joined the scientific staff of the Low Temperature Research Station in 1928 from the Muspratt Laboratory of Physical and Electro-Chemistry of the University of Liverpool, at the invitation of the late Sir William Hardy. From the outset of his career he was an individual worker, belonging to the less-common class of investigator who prefers to do most things for himself in the laboratory. Before the War Brooks made a name for himself in fundamental research, especially in the field of haematin pigments. Quite early in his career he was publishing work in the *Proceedings of the Royal Society* and the *Biochemical Journal*, and up to the outbreak of war he continued to produce a steady series of papers in his particular field of physical chemistry applied to biological systems. He then showed himself equally capable at quite the highest level in applying theoretical results to immediate practical objectives, namely, the dehydration of egg and the storage of dried material.

Brooks held an established position as the leading Government consultant in Great Britain on all matters concerned with the handling and storing of eggs. During the period 1943-47 he was lent to the then Ministry of Food for various periods, in the course of which he visited the Argentine, United States, Canada and Australia in connexion with the Ministry's programme for the manufacture of dried egg and, afterwards, for full-scale trials of sugar-dried egg production. Later he again visited Australia as a member of the British Food Mission. After the War the emphasis of Brooks's work turned from dried to shell eggs, and again his knowledge, skill and personality were called on by the Ministry of Food to help in the solution of problems in countries exporting eggs to Britain. In 1948 and again in 1950, he visited Poland in response to a request from the Polish Government for help in finding a solution to difficulties which had arisen in the preparation of frozen pasteurized egg in fulfilment of orders placed by the Ministry of Food. Brooks was the only person in Britain possessing the specialized knowledge for this task, and he was able to discover the cause of the trouble and suggest a solution completely satisfactory both to the Polish Government and the Ministry.

Although such calls for Brooks's services seriously interrupted his supervision of laboratory investigations, he continued to exercise a firm control over

these and to initiate and maintain lines of research which have been successful in several directions. Some of these lines, such as the storage of oiled eggs, had immediate industrial application. Others were aimed at discovering the mechanism of deteriorative changes which occur during prolonged storage such as, for example, the thinning of the white, the weakening of the yolk membrane, and the production of undesirable changes in flavour due to enzymic oxidation.

These were all problems needing deep exploration and a capacity for skilful research of the most fundamental nature. But for his deflection from 1940 onwards to the more applied aspects of his work, Brooks would almost certainly have established for himself as high a reputation in academic circles as he enjoyed in responsible quarters for his technical skill and knowledge of matters pertaining to eggs.

E. C. BATE-SMITH

NEWS and VIEWS

Air Ministry Appointments :

Mr. Hayne Constant, C.B., C.B.E., F.R.S.

MR. HAYNE CONSTANT has been appointed Scientific Adviser, Air Ministry. As a Fellow of the Royal Society and a member of the Aeronautical Research Council, and as director of the National Gas Turbine Establishment, Pyestock, he has for many years been closely connected with forward thinking in the aeronautical field. Born in 1904 at Gravesend, Kent, he went up to Queens' College, Cambridge, as a scholar in 1924 and graduated with first-class honours in the Mechanical Science Tripos in 1927. After a year's postgraduate research he entered the Royal Aircraft Establishment, and, after work on aircraft vibration and the performance of engines on weak mixtures, he pioneered work on the axial jet engine. His career has been mainly devoted to the advancement of the gas turbine as a prime mover, particularly for aircraft, in which sphere there has been such enormous advance in the past twenty years. In 1941, Hayne Constant was head of the Engine Department of the Royal Aircraft Establishment. In 1944, he linked forces with the Power Jets Whittle team as Power Jets, Research and Development, Ltd., and when that body became the National Gas Turbine Establishment he was deputy director. In 1948, he was elected a Fellow of the Royal Society and in the same year he succeeded Dr. (now Sir Harold) Roxbee Cox as director. In this capacity he was responsible not only for research but also for the centralization of the National Gas Turbine Establishment, bringing the Whetstone (Leicester) Whittle group to Pyestock, and the development of Pyestock into the biggest centre in Britain for gas turbine and ramjet test plant, including the Engine Test Facility. He received the Busk Memorial Prize of the Royal Aeronautical Society in 1932, and the Clayton Memorial Prize of the Institution of Mechanical Engineers in 1947. He was, from its inception in the war years, a member of the Gas Turbine Collaboration Committee with senior representatives of the British aero-engine industry. His views of, and predictions for, the gas turbine are published in his book "Gas Turbines and Their Problems", and in lectures and papers in many scientific and technical journals.

Mr. R. H. Weir, C.B.

MR. ROBERT HENDRY WEIR has been appointed director of the National Gas Turbine Establishment in succession to Mr. H. Constant. Mr. Weir, who has been principal director and director general of engine research and development since January 1, 1954, was born in 1912 and educated at Allan Glens

School, Glasgow, and the University of Glasgow, where he graduated B.Sc. with first-class honours in mechanical engineering in 1933. After an apprenticeship with Wm. Denny and Bros. Ltd., Dumbarton, he joined the Royal Aircraft Establishment in November 1933, where he was a member of the Engine Department until January 1939. He was then transferred to a post at headquarters in London, where he was engaged on aero-engine performance and work on pressurized cabins until December 1940. His next posting was to the Aircraft and Armament Experimental Establishment, Boscombe Down, where he spent a period of eighteen months on aero-engine liaison duties, and then transferred back to Engine Research and Development Headquarters in July 1942, for special duties on gas turbines. Mr. Weir was appointed director of industrial gas turbines in February 1950, and director of engine research and development in August 1952. He was made principal director of engine research and development in January 1954, which post was re-named director general of engine research and development in January 1959.

Ministry of Health : Sir John Charles, K.C.B.

SIR JOHN CHARLES, chief medical officer of the Ministry of Health, Ministry of Education and Home Office, is retiring on November 30. He is a graduate of the University of Durham, and achieved a high reputation as medical officer of health, Newcastle on Tyne. In addition to competent administration, he made important epidemiological, nutritional and public health inquiries. During the Second World War he was appointed a deputy chief medical officer of the Ministry of Health and in 1950 became chief medical officer. In Sir John's ten years of office he has given much attention to the development and consolidation of the National Health Service. He has seen a further notable decline in tuberculosis and diphtheria, and has encouraged effective vaccination against poliomyelitis. Among many other subjects which have engaged his attention are the mental health services under the new Act, the dental services, care of the aged and the progress of maternity and child welfare work. Sir John has visited various parts of the world in the interests of international health, being also chairman of the Executive Board of World Health Organization and president of the twelfth World Health Assembly. He gave the Bradshaw Lecture in 1948 and the Harveian Oration in 1955 to the Royal College of Physicians. He can look back with satisfaction on his tenure of office as medical adviser to three departments of State ; and in his retirement

may find time for further studies in medical history, which is one of his interests.

Dr. G. E. Godber, C.B.

DR. GEORGE EDWARD GODBER has been recently appointed to succeed Sir John Charles, with effect from December 1. Dr. Godber was educated at Bedford School and New College, Oxford, where he read physiology, and at the London Hospital. After qualifying, he served for twelve months as house physician in the professorial unit under Sir Arthur Ellis. Subsequent to gaining some experience of general practice and of local government service in Surrey, he joined the staff of the Ministry of Health in 1939 at the age of thirty. His first assignments there were concerned with the reception of evacuees in the reception areas and with the other early war-time responsibilities which fell to be discharged by the Ministry. Later he was responsible with the late Sir Leonard Parsons and Mr. Clayton Fryers for carrying out the combined Ministry of Health and Nuffield Foundation survey of hospitals in the Sheffield Region. Returning to Whitehall, he was concerned in association with other members of the Ministry's lay and medical staff in the various preparations which culminated in the launching of the National Health Service on July 5, 1948. Since he was appointed as deputy chief medical officer, his chief responsibilities have continued to lie with the several branches of the health service, and he has been active in collaborating both with the College of General Practitioners and the Society of Medical Officers of Health. He has been and continues a vigorous advocate of home care of the sick wherever practicable, and of active co-operation between general practitioners, local health authorities and the hospital and specialist services.

The Royal Society of Edinburgh: Officers for 1960-61

At a statutory meeting of the Royal Society of Edinburgh held on October 24, the following officers and members of Council were elected: *President*, Prof. E. L. Hirst; *Vice-Presidents*, Prof. T. Neville George, Prof. J. R. Matthews, Dr. T. R. Bolam, Dr. Douglas Guthrie, Dr. A. W. Greenwood, Prof. R. A. Rankin; *General Secretary*, Prof. Norman Feather; *Secretaries to Ordinary Meetings*, Dr. Mowbray Ritchie, Prof. A. E. Ritchie; *Treasurer*, Dr. J. R. Peddie; *Curator of Library and Museum*, Dr. R. Schlapp; *Members of Council*, Prof. E. G. Cullwick, Prof. G. Pontecorvo, Prof. M. M. Swann, Prof. V. C. Wynne-Edwards, Prof. H. A. Brück, Dr. H. R. Fletcher, Prof. G. L. Montgomery, Prof. W. L. Weipers, Prof. J. H. Burnett, Prof. C. F. Davidson, Prof. D. C. Paek, Dr. A. B. Stewart.

Applications of Electricity in Aircraft

THE Councils of the Institution of Electrical Engineers and of the Royal Aeronautical Society have recognized the growing need to provide a forum wherein engineers engaged respectively in the fields of electrical engineering and of aircraft construction can meet to discuss problems and new ideas affecting their common interest in aircraft electrical engineering. A Joint Committee, of which Prof. G. A. Whitfield, of the College of Aeronautics, Cranfield, is the chairman, was recently formed by the two organizations to consider ways and means of stimulating discussion of these matters, and it has now been

agreed that this can best be done by arranging for joint meetings of the two organizations in London and for the formation of joint groups in the provinces. It is intended that meetings of the joint groups should be informal and in the nature of colloquia, designed to interest technicians as well as aeronautical and electrical engineers. In order to launch the scheme there will be an inaugural meeting at the Institution of Electrical Engineers, Savoy Place, London, W.C.2, on November 11, at 5.30 p.m., when Viscount Caldecote will deliver a lecture on "The Future of 'Electrics' and 'Electronics' in Aircraft and Guided Missiles".

Department of Scientific and Industrial Research: Report on Shipbuilding

IN answer to questions in the House of Commons on October 27, regarding the publication of the Council for Scientific and Industrial Research's report on shipbuilding, Sir David Eccles, as representing the Minister for Science, said that the report was the subject of confidential discussions between the Council and representatives of the Ministry of Transport and the industry. The question of publication, which was one for the Council, would not arise so long as these discussions were in progress, but the Council intended to publish a statement as soon as these discussions were concluded. In reply to a further question, Sir David said that the current grant to the Parsons and Marine Engineering Turbine Research and Development Association amounted to £70,000 in consideration of the £210,000 raised by the industry, and the grant for next year would be on the same terms.

Russian Chemical Reviews

THE Russian *Uspekhi Khimii* is being published in translation as *Russian Chemical Reviews* by the Chemical Society with the support of the Department of Scientific and Industrial Research. The first issue has appeared and contains four review articles, on the chemical action of ultrasonic waves on macromolecules, developments in the chlorination of saturated hydrocarbons, the hydrides of the rare-earth metals, and the chemistry of quinuclidine derivatives. These are excellent surveys of the subjects, with extensive references to papers in Russian and other languages, and the translation appears to have been very well done. The translation is described as cover-to-cover, but reviews in the original which are translations from foreign periodicals are, with few exceptions (for example, Chinese sources), not included. The subscription rates are £12 (United States \$6 dollars), with a reduced rate for libraries of universities and technical colleges of £9 (27 dollars) per annum, including postage. Orders should be sent to Cleaver-Hume Press, Ltd., 31 Wright's Lane, London, W.8.

Checking Accidents In Factories

UNDER the title "Guide to Statistics collected by H.M. Factory Inspectorate" the Ministry of Labour has issued a booklet giving details of the methods of collection and compilation of the statistics, and of the systems of coding and classification which permit analysis of further information as and when required (Pp. i+41. (London: H.M. Stationery Office, 1960.) 4s. net). These statistics are based on the reports of accidents made by occupiers of factories and by certain other employers in accordance with

Section 64 of the Factories Act, 1937. The circumstances in which reports are required are detailed, and copies of the prescribed forms are appended to the booklet and also of the tables used for classifying the information. The booklet describes in detail how this information is examined, classified and given a coding to permit subsequent analysis.

Grants for Field Work In Natural History

GROUPS of local naturalists often find themselves held up for lack of specialist advice on how to tackle their problems. To help its members, the Council for Nature approached the Carnegie U.K. Trust, which has now agreed to set aside a fund from which it will make grants to approved societies for assistance with field work. These grants will be made on recommendations submitted by the Council for Nature and will be contributions towards expenditure incurred in carrying out specific projects that give amateurs experience of field work in natural history under skilled direction. Approved expenditure is likely to include fees paid to experts for instruction and leadership, the incidental expenses of such people and the cost of essential equipment subject to certain conditions. Grants will not be available for the expenses incurred by members of societies taking part in any scheme or for the general support of a society. Full particulars of the conditions for the award of grants can be obtained from the Carnegie U.K. Trust, Comely Park House, Dunfermline, Fife, or from the Council for Nature, 41 Queen's Gate, London, S.W.7.

The Wellcome Trust :

Grants for Medical Research

DURING the six months from March 1 to August 31 the Wellcome Trustees accepted the following applications for major grants to assist medical research. Together with smaller grants totalling £41,000, and Wellcome research travel grants, totalling £17,000, the allocations by the Trustees in this period exceeded £420,000. The grants were allocated as follows: £50,000 to the Middlesex Hospital Medical School, University of London (Prof. C. A. Keele), for a suite of Wellcome Research Laboratories in the Pharmacology Department of the new Medical School building; £50,000 to the Massachusetts General Hospital, Boston, to establish a Wellcome research professorship for ten years; £61,000 to the Medical Research Council, to construct a laboratory and housing accommodation for an Epidemiological Research Unit in Jamaica, also £60,000 to provide five Sir Henry Wellcome research travelling fellowships for five years; £40,000 to McGill University, Montreal, Canada, to extend the support of the Wellcome Research Department of Anaesthesia for a further five years; £17,000 to the University of Pennsylvania, to extend the support of the Wellcome associate professorship of research in anaesthesiology for a further three years; £16,000 to Trinity College, Dublin (Mr. K. M. Shaw), to construct and equip an experimental surgery unit and an animal house; £16,300 to the University of Oxford (Sir George Pickering), to construct an animal house for the use of workers in the Department of the regius professor of medicine; £6,000 to the Postgraduate Medical School, University of London (Prof. J. McMichael), to equip a cardiac catheterization research laboratory in the Department of Medicine; £10,000 to the University of Birmingham, Department of Biochemistry (Prof. S. V. Perry), for equipment to investigate the nature

and functions of the proteins of brain and muscle; £5,500 to St. Mary's Hospital Medical School, University of London (Prof. R. R. Porter), for an analytical ultracentrifuge to investigate the structure of antigens and antibodies.

In addition the Trustees made grants totalling £21,800 for special research apparatus of various kinds to Prof. R. Woolmer, Department of Anaesthesia, Royal College of Surgeons of England; Dr. G. A. Kerkut, University of Southampton; Mr. H. A. Sissons, Institute of Orthopaedics, University of London; the Agricultural Research Council's Virus Research Unit, Cambridge; Dr. K. S. Dodgson, Department of Biochemistry, University College of South Wales and Monmouthshire; Prof. O. L. Wade, The Queen's University, Belfast; Prof. G. A. H. Buttle, School of Pharmacy, University of London; Prof. J. W. Howie, University of Glasgow; and Prof. H. Heller, University of Bristol. A grant of £1,000 to purchase special equipment for high-altitude research was made to Dr. L. G. C. E. Pugh, physiologist to the Himalayan Scientific and Mountaineering Expedition, 1960-61.

Announcements

PROF. ARNE TISELIUS, of the University of Uppsala, Nobel laureate in chemistry (1948), has been appointed president of the Nobel Foundation.

THE Medical Research Council has recently established the following new research units: the Gastroenterology Research Unit at the Central Middlesex Hospital under the direction of Dr. E. N. Rowlands; and the Unit for Research on the Chemical Pathology of Mental Disorders in the Department of Physiology, University of Birmingham, under the honorary direction of Prof. I. E. Bush.

THE Institute of Biology, with the support of the Eugenics Society, has instituted an annual Darwin Memorial Lecture in human biology. The first lecture will be given by Dr. C. E. Ford of the Medical Research Council's Radiobiological Research Unit on "The Cytogenetics of Sex in Man". The lecture will be given in the lecture hall of the British Museum (Natural History), Cromwell Road, S.W.7, at 5.15 p.m. on November 23 and is open to the public.

THE annual exhibition of the Institute of Physics and the Physical Society will be held at the Royal Horticultural Society's Old and New Halls, Westminster, London, S.W.1, during January 18-20, 1961. During the exhibition, the following discourses and demonstration lectures will be given in the New Hall: January 17, "Hydrodynamics Research", by F. S. Burt (Admiralty Research Laboratory); January 18, "The Physics of the Ocean", by Dr. G. E. R. Deacon (National Institute of Oceanography); January 19, "Some Physical Problems in Travelling at Supersonic Speed", by Dr. F. P. Bowden (Laboratory for the Physics and Chemistry of Solids, Cambridge). Further information and tickets can be obtained from the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

ERRATUM. We regret that in the communication entitled "Evidence for the Identity of Natriferin, the Frog Water-Balance Principle and Arginine Vasotocin", by Prof. Wilbur H. Sawyer, in *Nature* of September 17, p. 1030, there is a mistake in the table; the right-hand heading should read: "Activities (μ /mgm. dry weight)".

SCIENCE BY THE UPPER FORM IN SCHOOLS

AT the annual meeting of the British Association for the Advancement of Science the section devoted to matters of general scientific interest, Section X (Assembly of Corresponding Societies), has for some years provided an opportunity for sixth-form scientists in local grammar and public schools to present papers on scientific studies carried out as a result of group or individual investigation. One whole morning session is set aside to allow the presentation of four topics, and large adult audiences flock to listen to the young embryo scientists.

This year at Cardiff, "Science by the Upper Form" was represented by Robert Riden, of Cardiff High School for Boys, who read a paper on "The Caves of South Wales"; Colin Rees, of Cathays High School for Boys, who discussed "The Increase of Herring Gulls at Worms Head, Gower, and its Effects on the Razor Bill and Guillemot Populations"; Glanffrwd Phillips and Clive Davies, of Ferndale Grammar School, Glamorgan, who presented a joint report on investigations into the presence of "*Craspedacusta sowerbii*—Fresh Water Medusa of *Microhydra*" in Darran Lake, Ferndale, and by Roger Williams, of Tredegar Grammar School, Monmouth, who surveyed the vast subject of "Astronomy" in half an hour.

Each talk was admirably illustrated with slides or projected photographs as well as by other visual material.

Robert Riden gave a vivid account of his adventures in exploring a number of caves of different types which border the South Wales Coalfield. He indicated their relationship to the geology of the coalfield, gave details of their structure and physical grandeur, with particular reference to three to be found in Breconshire, in Carmarthenshire and in Gower, and showed how young people with a spirit of adventure and a disregard for the discomforts to be faced could carry out much useful exploration underground, providing their expeditions were properly organized.

Colin Rees, with the help of some delightful coloured slides, exposed the ruthless habits of the herring gull on Worms Head in the Gower Peninsula. He unfolded an interesting story of variations in the population of bird life on the headland over the past twenty years, beginning with the rapid decline of the gull population during the war years due to human raids on the eggs as an additional item of food until rationing came to an end in 1947. The eggs of razor bills and guillemots escaped as they nested on the inaccessible cliff face, so that these birds multiplied at the expense of the herring gulls. But when the eggs of the herring gull were no longer in demand it reasserted itself very rapidly, laying, as it does, three times as many eggs a year and nesting wherever it can at the expense of the razor bills and guillemots, until herring gulls were once more swarming over the headland by 1959. To-day, Colin Rees stated, there are 150 pairs of herring gull to about 100 pairs of guillemots and 50 pairs of razor bills—he considered that the herring gull would go on increasing while the others would remain in equilibrium. He gave some interesting information about the feeding and nesting habits of the various birds, discussed the dangers of oil pollution, and showed how the prolonged and intensive study of one particular area of a

coastline can bring much valuable information about the habits in general of certain birds, the inter-relationships between the species, and the effects of human interference on their lives and numbers.

The third topic of the morning concerning the fresh-water medusae found in 1959 in the Darran Lake, Ferndale, was illustrated by some excellent diagrams prepared by Pamela Evans and Moira Morgan of the same school as the speakers, Glanffrwd Phillips and Clive Davies. There was evidence throughout of careful preparation and good group organization by the senior biology mistress, Miss M. G. Lewis, who had also been responsible for the investigations in the field. The paper gave an account of the discovery of small, transparent jelly-fish-like creatures in the Lake near the school at the height of the very dry summer of 1959. At first thought to be sea urchins, the creatures were eventually identified as medusae of *Microhydra*. Evidence was found of their previous location in other parts of Britain on rather rare occasions, always associated with hot, dry summers, but no clues could be discovered to account for their appearance at Ferndale in spite of much careful investigation of all the relevant factors. The series of slides revealed the wonders of the structure and variations in the shape of the medusae and showed how they reproduced by forming simple buds. Microscopic specimens were also available for examination. It was a well-presented topic, indicating how much useful research can be carried out as the result of the chance discovery of one small strange creature in a lake.

The final paper was a discourse on "Astronomy" by Roger Williams. It was a quite masterly survey of this vast subject within the short time at his disposal and ranged from the history of the science to the analysis of the rival theories of the origin of the universe—"the explosive hypothesis" and the theory of continuous creation. Without being drawn into any religious controversy, Roger Williams pointed out that it is "no more absurd to postulate the supernatural as always creating than to contain the creative act to a single instant". He went on to consider the techniques at the disposal of the modern astronomer, referred to the importance of the work of the amateur, and thought that while inter-planetary exploration by man could not be far away it was not likely to provide us with many new clues as to the origins and structure of the universe. The pursuit of research into its mysteries will long remain of the utmost import to the pure astronomer, but Roger Williams concluded that the problem of what to believe and what not to believe must always remain a matter for the individual, unmodified by scientific knowledge.

Thus the session, "Science by the Upper Form", ended on a philosophical note. It is good to know that some sixth formers not only study their text-books, and listen to the experts, but also carry out their own investigations and learn to think for themselves. In encouraging these habits among our young scientists still at school, the British Association in this and many other ways is doing a notable work for the better understanding of science by the younger generation. "Science by the Upper Form" to-day may be the basis for scientific advancement to-morrow.

G. S. CAMPBELL

THE TENTH CANADIAN HIGH POLYMER FORUM

ON September 7, some 170 scientists drawn mainly from Canada and the United States began a two and a half day conference on natural and synthetic macromolecules, under the general chairmanship of Dr. L. A. McLeod. As Dr. Sivertz reminded the conference, the study of high polymers in Canada, which was already important in relation to the large pulp and paper industry, received further impetus when, in 1942, Canada became a joint partner with the United States in the manufacture of synthetic rubber. A small working party drawn from the universities and industry was then set up, and from this developed open conferences and finally the Canadian High Polymer Forum was constituted and held its first meeting in 1949. Since that date meetings have been held at almost yearly intervals, and these have been characterized by informal and intimate discussion of contributed papers on a variety of topics. The meeting reported on here was the tenth in the series, and among other activities was marked by a banquet at which the mood of the principal speakers combined reminiscence with planning for the future.

Perhaps an outsider may be permitted to say that the meetings have not only served their regional and national purpose with particular success but have also been of wider value and importance, and that it is therefore entirely appropriate that the Canadian High Polymer Forum should be host to the International Symposium on Macromolecular Chemistry at Montreal on July 27–August 1, 1961. The relative merits of the small discussion group and the large conference with unrestricted membership have often been argued¹ and it will not be surprising if on the basis of its experience of earlier forums the organizing committee attempts to preserve the advantages of the former at the Montreal meeting. The eleventh Forum will not be held until the autumn of 1962 or the spring of 1963.

Twenty-four papers, all of which cannot be mentioned here, were presented at the tenth Forum. Five of these were concerned with ionic polymerization of unsaturated hydrocarbons. From these it appeared that rate constants for some of the individual steps in both cationic and anionic polymerization are now becoming available and it should not be long before coherent kinetic and mechanistic patterns emerge. Thus Dr. P. H. Plesch gave a value for k_p for the titanium chloride catalysed polymerization of isobutene in methylene chloride at -60°C . and values of the Arrhenius parameters of the spontaneous termination, monomer transfer and water transfer reactions relative to those for the propagation reaction, from which it appeared that monomer transfer is the last chain-breaking reaction to survive at low temperatures. Dr. A. M. Eastham gave an account of interesting attempts to study the initiation reaction free from the complications of propagation by an investigation of the kinetics of the geometrical isomerization of but-2-ene in ethylene dichloride induced by boron trifluoride-methanol mixtures. The results seem to show rather surprisingly that an adduct of but-2-ene, methanol and two molecules of boron trifluoride may be involved. In a rare, but

most welcome, contribution from one of the pioneers (R. M. Thomas) of cationic polymerization three new important findings were reported. The first was a medium for achieving liquid-phase cationic polymerization of isobutene at -185° , the second the demonstration by carbon-14 tracer techniques of solvent-fragment incorporation in the polymer and the third was the existence of an 'inversion' temperature of about -45° , above which the degree of polymerization of polyisobutene produced by aluminium chloride catalysis increases with monomer concentration and below which it decreases. This last result provoked much discussion, and mechanisms of chain termination involving two monomer molecules were advanced. Prof. M. Szwarc described a capillary flow method involving contact times in the range 0.2–1.5 sec. for measuring the k_p for anionic polymerization of styrene in tetrahydrofuran solution with Na^+ as the counter ion, and also the preliminary results obtained, together with the relative efficiency of water and methyl iodide as chain terminators. An elegant spectrophotometric method for measuring the relatively slow reaction of lithium butyl with styrene was described by Drs. S. Bywater and D. J. Worsfold. The definite but unexpected result was obtained that, contrary to earlier work, the rate of the initiation reaction is proportional to $[\text{styrene}]^{1.0} [\text{Li Bu}]^{0.15}$, whereas the rate of propagation is proportional to $[\text{styrene}]^{1.0} [\text{Bu (styrene)}_n \text{Li}]^{0.5}$. It seems that a six-fold aggregate of lithium butyl and bimolecular association of growing $\text{Bu (styrene)}_n \text{Li}^+$ ion pairs must be involved in reactions in the lithium butyl catalysed polymerization of styrene. The latter association was much discussed in relation to earlier and later contributions (especially that of N. Nikolov) and generally agreed to be important in more concentrated solutions.

Free-radical processes received due measure of attention particularly in relation to unusual phenomena in solid systems. Thus the effect of sulphur-containing antioxidants is promoted not only by carbon black but also by polyacenes, diphenylpolyenes and substances capable of generating quinonoid structures. The effect was ascribed by the Bell Telephone Laboratory workers to formation of π -bond complexes between the promoter as acceptor and thiyl radicals as donors, thereby reducing the reactivity of the latter as hydrogen abstracting agents. Dr. R. J. Ceresa showed that the kinetics of the swelling of chemically cross-linked or molecularly entangled polymers by vapours followed similar courses, showing discontinuities to be associated with mechanical rupture of chains or the cross-links since the use of vinyl monomers as swelling agents leads to the formation of block copolymers. The hitherto somewhat puzzling phenomena connected with the polymerization of vinyl monomers in aqueous solution were discussed, and shown to be approaching rational codification based on the mutual compatibilities and the water solubilities of monomer and polymer, and the susceptibility of soluble polyradicals to oxidative and reductive termination by ions of metals of variable valency. The rate constants of the growth and termination processes of the soluble

radicals are not too dissimilar from those in non-aqueous media and are quite independent of those of any longer-lived radicals in suspended polymer particles.

Full characterization of a solution of a polymer requires a knowledge of the structure, sizes and shapes of all the polymer molecules present and of its equilibrium properties as manifested in partial molal values of thermodynamic functions of solvent and solute. Many of the papers were concerned with this topic in one or other form. One, by Drs. W. H. Beattie and J. T. Bailey, was a timely cautionary reminder, generally acknowledged, of the need for a sharpening of our perception of the significance of the number, weight, Z and $Z + 1$ averages obtained from light scattering. Another, by Dr. W. Cooper and his associates of the Dunlop Rubber Co., Ltd., showed that second-order virial coefficients obtained from light scattering measurements on polybutadiene are strongly dependent on chain branching and revealed that the branch points are preferentially susceptible to mechanical breakdown. One of the most exciting contributions was that in which Prof. W. Heller of Wayne State University described his attempts to "walk around" macromolecular particles oriented in a streaming solution by observing the light which they scatter when illuminated from chosen directions. Already this fascinating but technically very difficult approach has not only indicated the shape of rigid particles but has also given insight into molecular elasticity by providing indications of the change of shape of flexible coiled macromolecules under the influence of shearing forces. If this method could possibly be extended to the use of polarized light an immensely powerful tool would become available. A further paper on polymer solutions by Dr. B. E. Conway dealt with the thermodynamics of the polar system polyoxypropylene glycol in methanol. The decrease in hydroxyl content with increase in molecular weight of the polyoxypropylene glycol leads to a change of sign in the heat of mixing; the experimental entropies and free energies of mixing can be accounted for by the Munster theory, which takes into account specific solvent orientation effects.

A number of the authors described the application of new experimental techniques to the solution of polymer problems. Dr. L. A. McLeod has fractionated elastomers such as *cis*-1,4-polybutadiene using elution chromatography, and Dr. Bacon Ke showed that differential thermal analysis is not only useful

in determining transition temperatures and heats of fusion of simple polyamides but may also give information concerning the structures of copolymers. Dr. W. Prins described a versatile osmometer which is capable, among other things, of measuring the de-swelling of polyelectrolyte gels. In this application the gel and solvent are separated by a porous stainless steel disk of porosity 5–65 μ , and the change in gel volume is measured when pressures of up to 200 atmospheres are applied to the gel phase.

Some interesting developments in the field of new polymers and copolymers were described. The strong and highly extensible elastomers produced by the incorporation of 2,4-toluene diamine in copolymers of polyoxypropylene glycol and 2,4-toluene diisocyanate were discussed by A. J. Havlik of the California Institute of Technology. Poly (5-methyl, 3-vinyl, oxazolidine-2-one), of which the surprising properties in water were reported by W. E. Wallis at the ninth Forum, forms strong complexes with a wide variety of organic compounds. The complex with phenol in which one phenol molecule may be bound per monomer unit in the polymer owes its strength to hydrogen bonding, but more unusual are the fairly strong complexes of the polyoxazolidinone with methyl bromide and bromine.

It is a tradition of these meetings to have a guest speaker who delivers the Conference lecture. This year the speaker was Prof. F. S. Dainton and his topic was "Why Polymerization Occurs". The central theme was that addition polymerization, which is usually regarded only from the point of view of the kineticist, is merely the aggregation of freely translating monomer molecules into larger molecules in which the basic units are joined by primary chemical valencies. Except in the nature and strength of the inter-unit linkage it is thus entirely analogous to physical aggregation processes such as condensation and crystallization and like these can be examined thermodynamically. The now familiar¹ notions of 'ceiling' and 'floor' temperatures, monomer-polymer equilibria and metastability phenomena were treated by the lecturer in relation to a wide range of systems. Recent calorimetric values of heats of polymerization and the entropies of polymers were used to illustrate the large effects on the heats and the minor effects on the entropies of polymerization of certain structural groupings in the monomer.

PHILOSOPHY OF SCIENCE

THE British Society for the Philosophy of Science held its fifth annual conference at Wills Hall, University of Bristol, during September 23–25. The four formal meetings and discussions, organized by Dr. Mary Hesse (Cambridge), were attended by fifty members and guests.

At the first meeting, with Prof. H. Heilbronn (Bristol) in the chair, two papers on the relation between pure and applied mathematics were read. Accepting the views of Frege, Cantor and others that the concepts of pure mathematics are exact, and of

Waismann and others that empirical concepts are inexact, Prof. S. Korner (Bristol) introduced a new generalized logic which embraced relations not only between exact concepts but also between inexact concepts and between exact and inexact concepts. He showed that 'purely exact' and 'internally inexact' concepts, as he defined them, could be identified with pure mathematical and empirical concepts respectively, and that they were logically unconnected. He thus described the application of mathematics as a threefold process: inexact empirical concepts are

replaced by exact concepts, exact conclusions are then deduced and, finally, the exact mathematical concepts are replaced by empirical concepts.

Prof. R. L. Goodstein (Leicester) traced the evolution of formal systems, using the development of geometry, mechanics and arithmetic to exemplify his thesis. The stages of evolution were successively the formulation and application of rules, the discovery of relations between rules and development of the concept of proof, the analysis of the rules of proof (metamathematics) and, finally, formal codification of metamathematics. He concluded that in applying mathematics we retrace its evolutionary development, replacing theorems by statements of observation. A mathematical proposition thus has a dual role. The ensuing lively discussion centred on the part to be taken by Korner's generalized logic in clarifying the problem, and on the strangeness of the fact that the exact concepts of pure mathematics could sometimes be successfully applied to the 'open-textured' concepts of empirical science.

Echoes of this first discussion were heard next morning when the theme was the relation between universality and necessity. Mr. W. C. Kneale (Exeter College, Oxford) gave a critical historical review of the question whether necessity can be defined by reference to universality. He traced three attempts at such definition: that, derived from Hume, in which necessity appears as a by-product of arguments the major premises of which are universal statements about Nature; that, derived from Bolzano and recently revived by Tarski, in which necessity is based on the universal validity of patterns of argument in which the only essential words are logical; and that, propounded by Popper in an appendix to "The Logic of Scientific Discovery", in which a Leibnizian reference to possible worlds seems to be related to a modified Bolzano-Tarski theory. Having explained the difficulties he found in all these reductionist programmes, Kneale advanced his own views that formal logic is pure theory of necessitation, that necessity is a fundamental notion, and that (with Wittgenstein) "all necessity is logical".

The second paper was given by Dr. I. Lakatos (London School of Economics), who first analysed the differences between the arguments of Popper and Kneale on both the ontological and epistemological planes. His witty theological formulation of the controversy, in which he sided more with Popper than with Kneale, included the startling credo that "the natural laws uttered by God were of infinite length" (and that therefore all universal statements, whether contingent or necessary, are false) and then he summarily dismissed the controversy as metaphysical and therefore meaningless. As a fallibilist, not only in science but also in logic and mathematics also, he could only regard both Popper and Kneale as mistaken in their "epistemological optimism", different though the forms of their optimism might be.

The chairman, Mr. J. W. N. Watkins (London School of Economics), then offered for discussion a model neatly designed to emphasize the conflicting views that had been propounded. In discussion, attempts were made to clarify the relation between logical and physical necessity. Do they form a linear continuum? Or are they homogeneous? But before complete clarification had been achieved, Dr. Lakatos silenced all further discussion by proving that any proof refutes the proposition it proves!

After strenuous discussion of closely knit philosophical arguments, the members turned with relief

and pleasure to view the intriguing optical devices used by Mrs. M. L. J. Abercrombie (Guy's Hospital) to illustrate her paper on learning to perceive. The chairman was Prof. J. E. Harris (Bristol). Mrs. Abercrombie explained that perception is a process of interaction between the observer's sensory input and his store of previously acquired information. In this interaction only parts of the total information available are used by the observer, selection being made both from the field observed (clues) and from the store (schemata). The observer makes a guess about what he perceives, acts on his guess and modifies it as other clues and other relevant schemata interact. She described how training to improve perception is possible by reference to her recent experiments in training medical students to improve their skill in diagnosis.

The second paper was given by Dr. M. H. Pirenne (Oxford), who described his experiments to determine the threshold intensity of light visible to the human eye. The physical and psychological factors impeding exact measurements were explained. The subject's eye had to be fixed and adapted to darkness; the subject had to be willing to co-operate and to be trained and tested for reliability. Difficulties were caused by day-to-day variation of response and by the phenomenon of 'subjective light'. There was not a sharp transition from visibility to invisibility as the energy of a light-flash was decreased, and the threshold was defined by an arbitrary statistical measure in the range of critical intensities. His results showed that the human eye could detect flashes of about 100 quanta in the narrow band of blue-green wave-lengths to which the periphery of the retina was most sensitive. Of these 100 quanta in the light-flash, only about 10 reached the retina and were there distributed among about 500 rods.

Discussion of these two papers was divided between questions of methodology and the implications of the empirical observations reported on current theories of perception. There seemed to be little evidence of, or need for, the pure sense-datum required in some theories.

At the final meeting, with Prof. M. H. L. Pryce in the chair, two theoretical physicists discussed the relation between methods of investigation and the characteristics of physical laws. In the first paper, Dr. D. Bohm (Bristol) criticized current views of the role of hypotheses in science. Implicit in Popper's view that scientific hypotheses could only be falsified was the assumption that questions giving answers in the form 'yes' or 'no' could always be put to Nature. But at the boundary of new scientific domains we knew the relevant questions only when the answers were already known. He also criticized the emphasis given to prediction and retrodiction in accounts of scientific method and expressed dismay at the degree of specialization enforced on scientists by the overwhelming mass of data which confronts them. It was important to establish a sound natural philosophy if the full potential of scientific method was to be realized.

The second paper, by Dr. P. W. Higgs (University College, London), reviewed the present untidy field of particle physics and discussed some of the implicit assumptions in this field that theoretical physicists were beginning to question. In particular, the effect of the gravitational field, hitherto regarded as negligible in strength compared with the other fields of particle interaction, seemed to deserve more careful exploration. In the discussion the main points were about the nature of the possible alterna-

tives to prediction and retrodiction as tests of the 'fitness' of hypotheses. What forms could 'diction' take? In what sense were the micro-particles of physics to be regarded as 'ultimate' or 'fundamental'? What exactly was meant by saying that one science or one branch of a science was 'reducible' to another? These were some of the many questions raised and left not wholly answered.

The Vice-Chancellor of the University of Bristol kindly invited the members to a sherry party at

Wills Hall on the Saturday evening. Thereafter, small informal groups, oblivious to everything except their own intense discussion, seemed to be generated spontaneously in all the many pleasant corners of Wills Hall and its gardens. At the conclusion of a stimulating week-end, expressions of thanks to the hosts at the University of Bristol, to the staff of Wills Hall and to the organizing secretary were more than mere formalities.

B. C. BROOKES

THE NATIONAL RESEARCH COUNCIL OF CANADA

THE forty-third annual report of the National Research Council of Canada, covering the year 1959-60, includes besides the report of the president, Dr. E. W. R. Steacie, of the nine divisions, two regional laboratories and the National Aeronautical Establishment and the financial statement, the annual report of Canadian Patents and Development, Ltd.*.

During the year the Council provided 8.7 million dollars in support of pure research in the universities, compared with 6.3 million dollars in 1958-59, of which 84 per cent was for 875 research grants and the remainder for 425 postgraduate scholarships, fellowships and associateships. The Council's scientific research staff of 658 included 137 postdoctorate Fellows, and in addition 916 technical personnel and 866 general service and administrative staff were employed. Claiming that neither the United States nor the United Kingdom possesses the clear but flexible delineation of administrative authority for science that exists in Canada, Dr. Steacie suggests that in Canada the responsibilities of the Minister for Science are constitutionally exercised by the chairman of the Privy Council Committee on Scientific and Industrial Research, and that in this respect Canada is forty years ahead of the United Kingdom. The problem in Canada is to ensure that scientific activities are so organized as to encourage the full development of the scientific and technical resources of the country. The first responsibility of a national science policy must be support of research in the universities, and the problem is how to maintain the strength and depth of the university science departments and, at the same time, satisfy the requirements of defence, industry and development of national resources with the vigour and competence demanded by international competition, without over-emphasizing technology at the expense of other activities. Dr. Steacie, noting that the Research Council has proved in the past to be an effective channel for supporting science in the universities, urges the need for a continual review of the support of science in the universities to ensure that procedures continue to evolve with the growth of science and changes in administrative practice. Further, while in Canada those departments of Government with administrative responsibilities for natural resources are responsible for the basic research to support their programmes, the Research Council has the function of ensuring the general adequacy of all remaining basic research, but Dr. Steacie stresses the importance of backing

Canadian industry by an industrial research effort as great as the scientific resources of the country can support.

Of the work of the Division of Applied Biology, the report notes a co-operative project with the Department of Agriculture on the design and performance of jacketed cold-storage rooms requiring fundamental knowledge of the factors determining low-velocity air-flow through shallow ducts, and a study by the Biometrics Section of agricultural meteorology as an extension of the statistical study of protein variability in wheat and wheat exports. Preparations were begun, including design of equipment, for an international expedition to study adaptation to cold by Eskimos. The work of the Division of Applied Chemistry on metals has gradually expanded during recent years, and now includes investigations of the effect of composition and structure on the optical and magnetic properties of a wide variety of alloys. A new technique, developed by the Division about eight years ago for the contacting of fluids and solids, has now been put into commercial operation in grain drying. The Division of Pure Chemistry has shown that ionization potentials of radicals prepared by pyrolytic reactions can be measured by electron impact in the mass spectrometer, and a study of the diffusion of chloride ions in single crystals of sodium chloride and of potassium chloride has shown that the diffusion is very sensitive to the presence of gross imperfections such as dislocations and grain boundaries in the crystals, while attempts to correlate the accumulated observations in the photo-oxidation of ketones have led to the conclusion that not only the rate but also the nature of the products of the reactions of methyl radicals with oxygen depend on the total pressure in the system as well as the presence of molecules containing easily abstractable hydrogen.

In the Division of Applied Physics a new group has been established for plasma research, work was completed in the interferometry laboratory which contributed to an international agreement to base the unit of length, the international metre, on a particular wave-length of the spectrum of an isotope of krypton, and the experiment to determine g , the acceleration due to gravity, by direct observations on a falling body was completed. The group in the Division of Pure Physics concerned with cosmic ray work is still devoting much of its efforts to international co-operation of the type started during the International Geophysical Year, and the development of a space research programme in Canada has permitted cosmic ray measurements with rockets flown to high altitudes. In the X-ray diffraction laboratory

* Forty-third Annual Report of the National Research Council of Canada, 1959-60, including the Annual Report of Canadian Patents and Development, Limited. (N.R.C. No. 5665.) Pp. 40. (Ottawa: Queen's Printer, 1960.)

important results are being obtained in the crystal chemistry of vanadium minerals and the stereochemistry and absolute configuration are being established for certain narcotics the structural formulæ of which have long been in dispute.

The Division of Mechanical Engineering records increasing emphasis on longer term investigations in thermodynamics and engine evolution, and many new propulsion problems in air transport are also being studied, especially those arising from vertical take-off and landing, while certain fluid mechanical aspects of nuclear reactors are being examined. At the National Aeronautical Establishment a substantial research effort has been redirected to problems of high-speed and very high-speed flight, and in particular an increasing effort is being applied to problems arising from very high temperatures. Much of the work of the Radio and Electrical Engineering Division

was concerned with defence projects, but the remainder of the programme was concerned with fundamental problems in electrical engineering and electronics, and a pressure gauge capable of measuring the atmospheric pressure at satellite altitudes was developed.

Work at the Prairie Regional Laboratory, Saskatoon, is devoted to a more thorough understanding of the plants and micro-organisms growing on the prairies; but to promote the development of oil-seed crops as alternatives to cereal crops an intensive study of the chemical structure of glycerides was undertaken. At the Atlantic Regional Laboratory, Halifax, where the most efficient way of drying the commercially important plant materials of the region has been studied, a semi-commercial scale batch dryer was developed and a continuous dryer is now being designed and constructed in co-operation with industry.

SAFETY OF YOUNG PEOPLE IN FACTORIES

PROBABLY the most important chapter in the annual report of the Chief Inspector of Factories for 1959* is one of two chapters dealing with subjects of interest without being necessarily restricted to the events of the year—that dealing with the prevention of accidents to young persons. While the consistent downward trend in the number of fatal accidents continued in 1959, there was an increase in the number of reported accidents, and the Chief Inspector is disturbed at the increase in the number of accidents to young persons, from 9,838 in 1958 to 11,001 in 1959. This rise is not due just to an increase in the numbers employed, and indicates clearly that redoubled efforts will be necessary to hold the rate of accidents to young people in check, as increasing numbers of school-leavers enter industry in the coming years. The present drive to train young persons in safe working must be intensified, he writes, not only by industry but also by secondary and technical schools and colleges.

The Chief Inspector, in his letter of presentation, points out that it is evident from the large number of accidents to the head and neck, to the feet and ankles and to the hands, that much more could be done to reduce such accidents by the wearing of suitable clothing, such as safety helmets, goggles, adequate footwear and gloves, and that careful attention would reduce dramatically the grand total of all reported industrial accidents. Young persons, particularly during the first year of employment, tend not to take adequate safety precautions and are more liable to run the risk of suffering injury than older workers. Ignorance of factory conditions and hazards, inexperience and natural curiosity, the desire to prove oneself, contempt for 'safety first' principles, liability to fatigue, and boredom leading to 'skylarking', can all be contributory factors, and there are many examples in the records of the factory inspectorate of the kind of accident in which youngsters are concerned for such reasons.

Young persons, it is clear, enter employment with a handicap, and it is the responsibility of their employers to help them overcome it by providing

sound training and careful supervision and by insisting on high standards of obedience to safety rules. Many of the large firms have, in fact, built up excellent organizations for this purpose, and in his annual report for 1951 the Chief Inspector, Sir George Barnett, attributed the considerable reduction in the post-war accident-rate mainly to this factor. Many managements, however, did not trouble to make allowances, and since then the rate of decrease of accidents to young persons has slowed down, and the decrease in the number of accidents to young persons is, moreover, proportionately less than the corresponding decrease for all employed persons.

While there have been several important pieces of legislation since 1937 affecting young persons employed in factories, such as prohibition or restriction of employment in certain dangerous or unhealthy trades, prohibition of employment on certain types of dangerous machinery or in carrying or lifting excessive weights, limitation of the number of hours a young person may work and the provision of medical supervision, the legal contribution must be supplemented by effective training and supervision, beginning in schools and colleges and continuing in industry. There are few places where the young can be prepared for work in the factory so well as in secondary school and college workshops and house-craft rooms. Classes there provide an excellent opportunity for showing how tools should be maintained and used, and machines properly guarded. The teacher, too, can inculcate a degree of safety consciousness and an acceptance of discipline in the correct use of machines and tools which is invaluable in factory life. As the Chief Inspector observed in addressing a conference on "Accident Prevention in Technical Colleges" at Blackpool in June 1958, arranged by the North West Regional Advisory Council for Further Education, his teachers are the best people to give the neophyte entering the factory the confidence that he requires.

The Chief Inspector did not suggest that safety should be taught as a subject *per se*, but rather that safety teaching should go hand in hand with the various subjects, and in the present report the Chief

* Ministry of Labour. Annual Report of the Chief Inspector of Factories on Industrial Health, 1959. Pp. iii+60. (Cmd. 1137) (London: H.M. Stationery Office.) 3s. 6d. net.

Inspector refers to encouraging developments as a result of the initiative of the North West Regional Council. The Council itself set up an Industrial Hazards Sub-committee, which organized three courses in accident prevention at Liverpool, Manchester and Preston, and afterwards the Cheshire County Education Authority established a permanent committee to deal with safety training in colleges in Cheshire, on which both industry and college staffs are represented. The general problem has also been discussed at a conference held recently in Glasgow, attended by a number of principals, heads of departments and teachers from technical colleges in Scotland, and addressed by senior members of the factory inspectorate.

Among the suggestions which found favour with the conference were publication of a safety code for each college; appointment of a member of the teaching staff to be specially responsible for safety matters; inclusion in examination papers of questions relating to safety; and close liaison between the technical colleges and inspectors of factories, who can give occasional lectures and advise on safety precautions. A pamphlet, comprising mainly speeches delivered at the Blackpool conference, has already been distributed to technical college teachers in the north-west region and received a wide circulation in other parts of Britain, but these efforts are only a beginning and, as the Chief Inspector now emphasizes, much more remains to be done if young people are to come into industry adequately prepared and the transition from school to industry is to be as smooth as possible. He urges that it is important for the success of this work that education authorities and individual principals and heads of departments at technical colleges should recognize the seriousness of the problem and the need to take steps to deal with it.

It might be added that this is a matter that could well be recognized as a professional responsibility by scientists and technologists, not simply when their own work as teachers or in industry brings them in direct contact with it, but through their

professional organizations. Their co-operation and guidance can sometimes make the decisive difference between success and failure, and this is no less true in respect of some of the suggestions for action by employers which are made in this special chapter of the Chief Inspector's report. Apart from care in picking young people for the work they are going to do, training schemes should include six particular points. The young worker should be taken around those parts of the factory where he will work and should be shown what the principal dangers are, how they arise and how to avoid them. A fully competent adult worker should directly supervise the young person's work during the initial period of training and the proper method of working any machine on which the youngster is to be employed should be illustrated in detail and the dangers associated with other undesirable methods explained. Departmental managers and other supervisory grades should be given clear instructions on accident prevention and on the need for keeping close control over the work of the young persons under their charge, and strict discipline should be enforced in the adoption of safe methods. Special safety propaganda should hammer home the important points and make young workers aware of the importance which is attached by the employer, and all in supervisory positions, to the principles of accident prevention.

Clearly not all these points concern either the scientist or technologist as such, but in many of them his interest and co-operation can be decisive factors. Moreover, as the report concludes, it is not only firms with large numbers of youngsters and great financial resources that can achieve substantial results. It is well within the capacity of managers and supervisory staffs in smaller firms to make the effort to see that their young recruits have a good and safe start in their chosen career, and many such managers and members of supervisory staffs, as well as teachers and departmental heads in technical colleges, are themselves likely to possess scientific or technological qualifications.

THE COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION IN AUSTRALIA

THE eleventh annual report of the Commonwealth Scientific and Industrial Research Organization in Australia, covering the year 1958-59*, notes a number of changes in organization.

The Division of Industrial Chemistry has become the Chemical Research Laboratories, with three Divisions, Chemical Physics, Mineral Chemistry and Physical Chemistry, and three independent Sections, namely, Cement and Ceramics, Chemical Engineering and Organic Chemistry. Similarly, the Wool Textile Research Laboratories have been renamed the Wool Research Laboratories, with Divisions of Protein Chemistry, Textile Physics and Textile Industry. The Soil Mechanics Section of the Division of Soils has become an independent section of the Organization and the unit of the Division of Plant Industry and Plant and Soil Laboratory, Brisbane, becomes an independent Division of Tropical Pastures, while the

former Radio Research Board Laboratory, Camden, New South Wales, has become an independent Upper Atmosphere Section. Collaboration with the universities has been further extended by the establishment with the University of Melbourne of a joint laboratory for research and soil mechanics at Syndal, Victoria, and of a Meat Research and Teaching Centre at the University of Sydney Animal Husbandry Farms, Camden, New South Wales. A Rice Research Station is being established on the coastal plains near Darwin, where studies will be made of nutrition and water requirements of rice and of possibilities for developing varieties well adapted to that environment. Two frigates, specially equipped for oceanographic survey work, are being made available to the Organization for periods of about 12 weeks a year, and this assistance will facilitate the more comprehensive and regular programme of observations which must be undertaken before a clear picture of the oceanography of the waters surrounding Australia can be developed.

* Eleventh Annual Report of the Commonwealth Scientific and Industrial Research Organization for year 1958-59. Pp. 181. (Canberra: Commonwealth Government Printer, 1960.)

In co-operative industrial research support of the Australian Leather Research Association, the Bread Research Institute of Australia, the Wine Research Institute and the Australian Coal Association (Research), Ltd., continued. New research projects sponsored by industry commenced during the year included investigation of solid lubricating materials derived from Australian beach sand minerals; development of methods for determining the oxygen content of cyanide solutions used in extracting gold from its ores; research on the colorimetric properties of pigmented materials; and the study of changes in shell egg quality during marketing. The design study for the proposed giant radio-telescope for the Division of Radiophysics has been completed, and the radio telescope is scheduled for completion early in 1961. During the year 24 junior and 26 senior postgraduate studentships were awarded as well as 14 overseas research studentships. Of the Organization's income

of £8,060,831 in 1958-59, £6,297,597 was from Treasury appropriation and £1,322,576 from the Wool Research Trust Fund Account. Of the expenditure of £7,538,477 on research activities, £776,186 was on animal health and production, £831,237 on the plant industry, £263,480 on food preservation and transport, £336,868 on forest products, £678,571 on chemical research, £198,144 on fisheries and oceanography, £657,310 on the National Standards Laboratory, £157,049 on building research, £403,453 on radio-physics, £446,402 on wool research, £203,276 on fuel research, £125,962 on wildlife survey, and £202,226 on land research and regional survey. Besides summarizing the work of the Organization during the year in nearly thirty different fields, the report includes details of the membership of the Council and its committees and of the professional staff of the Organization as well as a list of papers published during the year.

THE INSTITUTE OF PHYSICS AND THE PHYSICAL SOCIETY

The Physical Society

AT the extraordinary general meeting of the Physical Society held on July 5, in London, the reports of the council and the accounts for the year ended December 31, 1959, were presented and adopted and the special resolutions for the voluntary winding up and the transfer of the assets of the Society to the newly amalgamated body, the Institute of Physics and the Physical Society, were unanimously carried.

The year under review in the annual report is stated to have been very satisfactory from the financial point of view, with an overall excess of income over expenditure of £3,796. The Exhibition Contingency Fund was increased by £4,000 to £12,000, but the exhibition account still showed a profit of £1,966. The 1959 exhibition of scientific instruments and apparatus was held earlier in the year, January instead of March, but there was no falling off in the keenness of exhibitors to obtain space or in the attendance of visitors to the exhibition.

The "Handbook of Scientific Instruments and Apparatus", the catalogue of the exhibition, was in great demand and sold well. The flow of manuscripts for publication in the Society's *Proceedings* remained steady during 1959, but because of the printers' strike the volume of material published was less than in former years. 174 papers, 72 research notes and 25 letters to the editor were published, and 54 out of a total of 302 manuscripts received were rejected. Volume 22 of the "Reports on Progress in Physics", which was published during the autumn, was the largest for some years and contained fourteen articles. The sale of past issues of both *Proceedings* and the "Reports", as well as of reprints of individual articles in the "Reports", showed a marked increase. A list of the various lectureships, prizes and medals awarded by the Society during 1959 and their recipients is given in the annual report.

The lectures and the presidential address are published in the "1959 Year Book of the Physical Society". Brief reference is also made in the report to the activities of the Society during the year and

in particular to the conferences lasting two or three days which were held on various subjects in Birmingham, Durham, Edinburgh, London and Oxford. The attendances were usually between 100 and 300, with members of the Society forming the majority.

The Institute of Physics

An extraordinary general meeting of the Institute of Physics was held on July 5, 1960, in the Institute's House, 47 Belgrave Square, London, with the president, Sir George Thomson, in the chair. The first part of the meeting took the form of the annual general meeting and the fortieth annual report of the Board of the Institute of Physics was presented and adopted*. The meeting then considered three special resolutions concerned with the winding up of the Institute and the handing over of its property and its funds to the amalgamated body, the Institute of Physics and the Physical Society. The resolutions were carried unanimously.

The report records the continued growth of the Institute, both in the number of its members and in its activities in many fields, including education, scientific publications and conferences, symposia and meetings arranged by its branches and specialist groups. During the year, 933 applications for election or transfer to the various grades of membership were received, and the total membership increased by 445 to 6,754. Five technical colleges applied for recognition by the Institute as institutions having courses of work approved for the purpose of the membership regulations and all five were accepted.

Thirty-nine of the 119 candidates who presented themselves for the examination for the graduateship grade of membership were successful; 13 possessed university degrees and 26 the Higher National Certificate in applied physics. The fifteen question papers, together with the examiners' comments, were published in the September issue of the *Bulletin* of the Institute, and afterwards also as a pamphlet.

* Institute of Physics. Fortieth Annual Report of the Board of the Institute of Physics for the year 1959. Pp. 19. (London: Institute of Physics.)

New regulations and syllabuses for the graduateship examination, which will be in two parts, are to come into operation in 1962. There were 820 candidates from 46 technical colleges for the Ordinary National Certificate in applied physics and 296 from 23 colleges for the Higher Certificate.

A new edition of the booklet "The Scientific Education of Physicists", which gives guidance on training and a summary of information about the physics departments of all universities and recognized technical colleges in Great Britain, was published during the year. A symposium on "Current Developments in the Production of High Vacua" was held in London on April 17, and a two-day conference on "Some Aspects of Magnetism" in the University of Sheffield during September 22-24. Summarized accounts of the proceedings of the symposium and of the conference have been published in the *British Journal of Applied Physics*. Books published for the Institute included reprints of the first five monographs in the "Monographs for Students" series, and a new volume, "Mechanical Design of Laboratory Apparatus", by H. J. J. Braddick; "The Design of Physics Research Laboratories", the proceedings of a symposium arranged by the London and Home Counties Branch of the Institute; and a second edition of "Physics as a Career".

Details are given in the annual report of the amount of material submitted and published during the year in the Institute's two monthly journals, the *British Journal of Applied Physics* and the *Journal of Scientific Instruments*. The Journals Advisory Committee at its meeting, held during May, agreed that the scope of the *British Journal of Applied Physics* should not be limited despite the appearance of several new journals devoted to particular branches of applied physics. The circulation of the *Journal* continued to increase, but that of the *Journal of Scientific Instruments* showed a slight decrease for the first time for many years. The page size of the *Bulletin* was increased to conform with that of the two *Journals*, and the 324 pages of text, which contained about 22 per cent more material than the 336 pages of the 1958 volume, included twenty-five articles and 114 book reviews, in addition to Institute news.

The activities of the Australian, Malayan and the nine Great Britain branches, together with those of

the specialist groups of the Institute, are outlined separately in the report. Two conferences were held by the Australian branch in Melbourne, the second "Conference on Contemporary Optics" during February 25-27, and the "Solid State Physics Conference" during August 17-21. A new division was formed in the Australian Capital Territory. The Applied Spectroscopy Group held an all-day symposium on "Reviews of Recent Developments in Spectroscopy" in May; the Education Group an Easter conference on the teaching of science to children up to the age of fifteen; the Electronics Group a two-day meeting in October on the subject of noise in electronic devices; and the Non-destructive Testing Group the first joint conference with the Société Française de Métallurgie in Paris. The Stress Analysis Group undertook a new venture in April when it arranged a three-day international conference on stress analysis in Delft, Holland. Fifty-one papers covering a wide range of topics were presented, and a selection of the papers is to be published in book form.

The annual dinner of the Institute was held on May 5, at the Park Lane Hotel, London, when 265 members and guests were present. The speakers were the president, Sir George Thomson, Sir Keith Murray, Sir Harry Melville and Mr. O. W. Humphreys. The alterations to the Institute's House, which had to be postponed for reasons of economy, were completed during 1959, and the senior staff dining room which had been used temporarily as an office was converted into a committee/dining room. The furnishings and décor were provided for by friends of the Institute and from the bequest of Mrs. W. Phillips. The Institute's accounts show a substantial increase in members' fees and on the publication business. £3,450 was transferred from the Institute's accounts to the Endowment Trust Fund account, but this was only just sufficient to cover the cost of the scientific and educational activities carried out by the Fund for the Institute. The Benevolent Fund continues to be well supported by members, and a further donation, of £A.200 received from the Australian Branch's Spécial Fund and an additional payment of £258 in respect of tax recovered on payments made by the Trust set up under the will of the late Mrs. W. Phillips were very welcome. During the year £936 was paid out in assistance to ten cases.

FERAL MUNTJAC DEER (*MUNTIACUS* SPP.) IN THE WEST MIDLANDS

TWO species of muntjac deer, the Chinese (*Muntiacus reevesi*) and the Indian (*M. muntjac*), were introduced into England at Woburn Park, Bedfordshire, about the beginning of this century. Later they were kept at Whipsnade and at least two private zoos (Crowland Abbey, near Wellingborough, and at Broxbourne, Herts). During the past half-century, muntjac have been reported in Bedfordshire, Northants, Warwickshire, Bucks, Herts, Berks, Cambridgeshire, Huntingdonshire, Essex, Leicestershire, Middlesex, Norfolk, Oxon., Staffordshire and Suffolk. Only in the last five counties can it be stated as certain that the deer are established as a regularly breeding species at the present time.

The successful colonization by the muntjac of a wide area of Britain has taken place very largely without the knowledge of its human inhabitants. T. J. Pickvance and J. S. R. Chard have prepared an article directing the attention of naturalists and others to the presence of this small deer and indicating some of the problems involved in recording the distribution and habits of the muntjac (*Proceedings of the Birmingham Natural History and Philosophical Society*, 19, Part 1; 1960).

The muntjac is unlikely to become the object of measures of extermination. Unlike the larger species of deer, it does no harm to trees, and from places where it sometimes becomes a nuisance, such as market

gardens and allotments, it can be excluded by wire netting. Control will not prove difficult as it is easily caught, and, being a creature of habit in its movements, is not difficult to shoot. Its small size and retiring habits aid its unobtrusive spread. Thus, an increasing number of naturalists will be able to study this species which has an interesting form of territorial behaviour.

The main part of the article deals with records of the colonization by the muntjac of Warwickshire. These are typical of those gathered during surveys made with the view of determining not only the present distribution of the animal but also the rate and direction of colonization and the past history of the movements which have taken place.

NOMENCLATURE OF THE NICOTINAMIDE NUCLEOTIDE COENZYMES

By DR. MALCOLM DIXON, F.R.S.

Department of Biochemistry, University of Cambridge

THE nomenclature of the nicotinamide nucleotide coenzymes has been a subject of long-standing disagreement, and unanimity has not yet been reached. Several different systems are in use to varying extents.

Included with other subjects in the terms of reference of the Enzyme Commission of the International Union of Biochemistry¹ is the nomenclature of enzymes and of coenzymes, and during the past three years the Commission has been giving careful and detailed consideration to the question of coenzyme nomenclature in an effort to reach a generally acceptable solution. The question has also been considered by the Biological Chemistry Nomenclature Commission of the International Union of Pure and Applied Chemistry. A summary of the points involved and the reasons for the recommendations of the Commissions may be of interest.

Present Position

The situation that has to be faced is that, except perhaps in the United States, there is no unanimity about the naming of the two coenzymes. Four different systems are in use, although to very different extents, and the special difficulty of the position arises from the fact that the system that is most used is that which has the strongest objections from the chemical point of view. The four systems are: (a) cozymase and phospho-cozymase; (b) codehydrogenase I and codehydrogenase II (or codehydrase I and codehydrase II by some Continental writers); (c) coenzyme I and coenzyme II (abbreviated to CoI and CoII); (d) diphosphopyridine nucleotide (DPN) and triphosphopyridine nucleotide (TPN). The first system is probably the least, and the fourth the most, used at the present time. None of these systems is satisfactory, the first three because they are uninformative, the last because it is incorrect, as a number of reviewers have pointed out²⁻⁵.

There is rather more consistency among the journals than there is among authors of books and reviews. The *Journal of Biological Chemistry*, which had previously used both cozymase and coenzyme I, first used diphosphopyridine nucleotide in about 1940; and it has continued to do so, along with cozymase and coenzyme I, until about 1950, and as the sole form after that date. The *Biochemical Journal* used cozymase and coenzyme I, and did not permit diphosphopyridine nucleotide, until as recently as 1953, but since then has used the last name almost entirely. The index of *Chemical Abstracts*, however, still uses codehydrogenase I rather than DPN.

Di- and Tri-phosphopyridine Nucleotide

There would be no objection whatever to the use of the names diphosphopyridine nucleotide and triphosphopyridine nucleotide if they did not indicate chemical structures, but the main objection is, in brief, that not only do they fail to give the structure of the coenzymes properly but also that they are the chemical names of other compounds. It is somewhat like using the name 'methyl acetate' for pyruvate; the name indicates a structure, but it is the wrong structure.

The names are derived from, though not the same as, names introduced by Warburg⁶ in 1936 as convenient descriptions. The term 'pyridine nucleotide' was used, quite legitimately, to distinguish this class of compounds from purine nucleotides such as the adenine nucleotides. To distinguish the coenzymes from each other they were described as 'the diphospho-' and 'the triphospho-pyridine-nucleotide', at first with the definite article, although this was almost immediately dropped and the terms thereafter used as names in the German forms 'Diphospho-Pyridinnucleotid' and 'Triphospho-Pyridinnucleotid'.

'Diphospho-'. In 1939, F. G. Fischer⁷, in his review on the subject, pointed out that these names, though concise, were incorrect. According to chemical terminology, 'phospho-X' denotes X combined with an additional phosphate group; but the word 'nucleotide' already includes a phosphate group, thus a 'diphospho-(di)nucleotide' would contain four phosphate groups, and not two as does the coenzyme. Fischer suggested that, especially in relation to the accepted names of the analogous flavin nucleotides, the names 'Pyridine-Adenine-Dinucleotide' and 'Phospho-Pyridine-Adenine-Dinucleotide' would be clearer. They would have the advantage of showing that the compounds are dinucleotides containing adenine, which was not indicated by the earlier names. Probably because of the outbreak of war in the same year, these suggestions did not receive the attention they deserved.

'Triphospho-'. It was at first believed that the three phosphate groups of triphosphopyridine nucleotide were joined in line, as in adenosine triphosphate, so that the relationship between the two coenzymes would be analogous to that between adenosine diphosphate and adenosine triphosphate. When the true structure of triphosphopyridine nucleotide was determined by 1950 by Kornberg and Pricer⁸, it was found to be a monophospho-dinucleotide, so that the prefix 'triphospho-' became less appropriate.

'Diphosphopyridine-'. Perhaps the most serious objection arose when the names became anglicized,

Nicotinamide mononucleotide (NMN)	Nicotinamide—D-ribose—phosphate
Coenzyme I (CoI)	Adenine—D-ribose—phosphate
Diphosphopyridine nucleotide (DPN)	Nicotinamide—D-ribose—phosphate
Nicotinamide-adenine dinucleotide (NAD)	
Flavin mononucleotide (FMN)	isoAlloxazine—ribitol—phosphate —flavin—
Flavin-adenine dinucleotide (FAD)	Adenine—D-ribose—phosphate isoAlloxazine—ribitol—phosphate
Phospho-coenzyme II (CoII)	Phosphate
Triphosphopyridine nucleotide (TPN)	Adenine—D-ribose—phosphate
Nicotinamide-adenine dinucleotide phosphate (NADP)	Nicotinamide—D-ribose—phosphate

Fig. 1 Structures of nicotinamide and flavin nucleotides

first I believe in about 1940 in the United States. The form used by Warburg, namely, 'Diphosphopyridinnucleotid', was clearly intended to be taken in the sense of diphospho(pyridinenucleotide), as shown by the hyphen and the capital P. The introduction of a space before 'nucleotide' gave a form with quite a different meaning. The name 'diphosphopyridine nucleotide' means quite unambiguously a nucleotide of diphosphopyridine, that is, a substance of the structure diphosphopyridine—D-ribose—phosphate, and it is not surprising that the biochemists have often been criticized by the organic chemists for using such names.

'Dihydrodiphospho-'. For the reduced or dihydroforms, diphosphopyridine nucleotide and triphosphopyridine nucleotide yield names beginning with the undesirable prefix 'dihydrodiphospho-', which is a further objection.

'Pyridine-'. One may properly use the term 'purine nucleotides' for the whole class, but in referring to a particular nucleotide the name of the particular purine is used. One says 'flavin-adenine dinucleotide' and not 'flavin-purine dinucleotide'. Correspondingly the word 'pyridine' ought not to be used for the names of particular nucleotides, unless they are in fact nucleotides of pyridine itself. 'Pyridine' should not be used when 'nicotinamide' is meant. The coenzymes are nicotinamide compounds, and the corresponding pyridine compounds are inactive as coenzymes*. The diphosphopyridine nucleotide system of nomenclature causes great difficulty in the rapidly expanding work on analogues of the coenzymes. If the nicotinamide nucleotides are called 'pyridine nucleotides', what can one call the pyridine nucleotides? They surely cannot be called pyridine analogues of the pyridine nucleotides! The use of diphosphopyridine nucleotide forces the use in current literature of such terms as 'pyridine-DPN' and 'APDPN' (for acetyl-pyridine diphosphopyridine nucleotide), in which the word 'pyridine' occurs twice, although there is only one pyridine ring in the compound. This is a very real difficulty.

'DNP'. DNP is the accepted abbreviation for dinitrophenol, a reagent much used in work on the coupling of biological oxidation and phosphorylation. Papers on DNP often contain many references to DPN, and the similarity makes them confusing and difficult to read.

'FMN, FAD, NMN, —?'. Finally, the name diphosphopyridine nucleotide obscures the close and important analogy with the corresponding flavin compounds, shown in Fig. 1. Flavin-adenine

dinucleotide (FAD) is the same substance with the nicotinamide end changed into the flavin structure. Flavin mononucleotide (FMN) is the same without the adenylic acid half of the molecule. Nicotinamide mononucleotide (NMN) is the coenzyme without the adenylic acid. These three names and the corresponding abbreviations are quite generally accepted, and there is no suggestion that they should be changed. To complete the scheme we should expect NAD for nicotinamide-adenine dinucleotide, thus:

FMN	NMN
FAD	NAD

The use of DPN instead of NAD breaks the logic of the nomenclature.

Summary of Objections

To recapitulate, the main objections to the name diphosphopyridine nucleotide are: (a) the coenzyme is not a nucleotide of diphosphopyridine as the name indicates; (b) the name indicates the presence of four phosphate groups instead of two; (c) it does not indicate that the coenzyme is a dinucleotide or that it contains adenine; (d) the coenzyme is not a nucleotide of pyridine but of nicotinamide; (e) the pyridine nucleotides, to which the name properly applies, are inactive as coenzymes; (f) the use of the name for the nicotinamide compound makes it impossible to name the pyridine analogues satisfactorily; (g) the combination 'dihydrodiphospho-' in the name of the reduced form is undesirable; (h) the name is out of line with the FMN FAD NMN sequence and obscures the close chemical analogy with the flavin compounds; (i) the corresponding name triphosphopyridine nucleotide suggests a triphosphate structure rather than the actual monophospho-dinucleotide structure.

In view of the strong chemical objections, the Enzyme Commission felt itself unable to recommend the continued use of the DPN system of nomenclature, particularly as a satisfactory alternative was available. The difficulty is not a chemical one, for there is no doubt about what the substance is: it is nicotinamide-adenine dinucleotide. It is the psychological difficulty of bringing the correct name into use, when an incorrect name has become well established. The Commission fully realizes that it is taking a serious step in recommending a change, and that there is likely to be some opposition, perhaps especially in America, as there was in Britain when DPN replaced Co I. However, this moment, when a real effort is being made to bring the terminology of enzymology into order, is the right one to put the coenzyme nomenclature right also. It is probably the last opportunity there will be of doing so; if it is not done now, there is not likely to be another chance.

Some workers feel that the whole matter should be left optional, so that authors should be free to use any system they wish. The difficulty facing the Commission, however, was that, apart from the fact that it was given the task of dealing with coenzyme nomenclature, it also had to deal with the nomenclature of enzymes, and the names of a large number of enzymes depend on those of the coenzymes. It was therefore obliged to make a choice, in order to avoid the necessity for more than one systematic name for each of these enzymes.

Nicotinamide-adenine Dinucleotide

It has therefore decided to recommend that both Co I and DPN should be dropped, and that the

coenzyme should be known by its actual chemical name, nicotinamide-adenine dinucleotide, which may be abbreviated to NAD. It will be seen that this name avoids all the objections mentioned above, it indicates the structure of the compound, it brings out the analogy with FAD, and it makes it possible to name the analogues satisfactorily. The reduced form would be named dihydronicotinamide-adenine dinucleotide, which indicates correctly the part of the molecule that becomes reduced.

Nicotinamide-adenine Dinucleotide Phosphate

Triphosphopyridine nucleotide (CoII) might be named phospho-nicotinamide-adenine dinucleotide, but this is undesirable, for 'phospho-nicotinamide' is as incorrect as 'diphosphopyridine', and the reduced form would again have the 'dihydrophospho-' prefix. The recommended form 'nicotinamide-adenine dinucleotide phosphate' (NADP) avoids both these objections, and the extra P clearly indicates the formation from NAD by the addition of a phosphate group.

Coenzyme Analogues

Using the NAD system, the naming of the analogues becomes relatively simple and straightforward. For example, the pyridine analogue would be called pyridine-adenine dinucleotide, which might be abbreviated to PAD if desired. The deaminated form is at present called 'desamino-diphosphopyridine nucleotide', but this gives little idea of its nature, since the part of the molecule which is deaminated (the adenine) is not mentioned in the name. The obvious name for it is nicotinamide-hypoxanthine dinucleotide (NHD). The analogue of TPN in which the phosphogroup is attached to the 3'-position instead of the normal 2'-position is at present called '3'-triphosphopyridine nucleotide', which surely cannot be taken as indicating only one phosphate group attached to the 3'-position. The new system would give the natural name nicotinamide-adenine dinucleotide 3'-phosphate, perhaps abbreviated to NAD3P. Other analogues should cause no great difficulty. Abbreviations for the analogues are not being officially suggested; these are merely given as personal suggestions to illustrate the great advantages of the NAD system.

Possible Objections

It remains to consider whether the names now proposed for the coenzymes are in strict accordance with chemical terminology.

'Nucleotide'. Can nicotinamide mononucleotide and flavin mononucleotide strictly be termed nucleotides? If the definition of a nucleotide is restricted to substances that can be obtained from nucleic acids (that is, to purine and pyrimidine nucleotides), they cannot, because of the different bases present. Probably, however, nobody would wish to narrow the definition in this way, and it is much more reasonable to use the term to denote the chemical structure: base—pentose—phosphate. Clearly nicotinamide mononucleotide qualifies as a nucleotide.

The case of flavin mononucleotide is not so clear, for two reasons. In the first place, it contains not ribose but ribitol, so that the —CHOH— group in position 1 of the ribose is represented by a —CH₂— group in the flavin. However, the term nucleotide

is also applied to the deoxyribonucleotides, in which the —CHOH— group in position 2 of the ribose is replaced by a —CH₂— group. It is not unreasonable, therefore, to make the term cover both modifications, although the change in the 1-position is the more important, since it prevents ring formation. In actual fact, the flavin compounds have been universally called nucleotides for well over twenty years, and there is no suggestion that their nomenclature should be changed.

In the second place, the term 'flavin' includes not only the base but also the ribitol. Therefore the term 'flavin nucleotide' must be understood as a nucleotide containing flavin, rather than a nucleotide 'of' flavin in the sense in which NMN is a nucleotide of nicotinamide.

'Dinucleotide'. Finally, can nicotinamide-adenine dinucleotide and flavin-adenine nucleotide be strictly termed dinucleotides? A purist might hold that the term implies that the two mononucleotides are linked in the same way as are the nucleotides in nucleic acid, by a 3'-5'-linked phosphate group. However, it would seem reasonable to consider a compound formed by the simple union of two mononucleotides to be a dinucleotide, particularly as the two classes of dinucleotides only differ in the point of attachment of a single bond.

'Dipeptide' has been quoted as an analogy where the term implies a definite point of linkage, but the analogy is not a valid one. A dipeptide is not formed by the union of two mono-peptides, and the name is clearly based on different principles. A truer analogy would be 'disaccharide', which is used for a compound formed by joining two monosaccharides, without respect to the point of attachment.

Substances of the flavin-adenine nucleotide type have been called dinucleotides ever since their first discovery, and it is the only name available. It has probably appeared far more often in the literature in this sense than in the sense of the 3'-5'-linked compounds, and it would be unreasonable now to restrict its use to the latter type.

Conclusion

Such are the reasons which have led the Enzyme Commission of the International Union of Biochemistry to recommend the use of NAD and NADP. The Biological Chemistry Nomenclature Commission of the International Union of Pure and Applied Chemistry has also decided, after considering the possible alternatives, to recommend these names in place of the existing systems. Preliminary experience has shown that, even by those whose first reaction is to express a preference for the retention of DPN, the new names are very quickly found to be attractive and satisfactory. It is hoped that when they become the official recommendations of both International Unions the journals will give a lead in their adoption.

STABILIZATION OF SEDIMENTARY COASTLINES

By DR. R. SILVESTER

Department of Civil Engineering, University of Western Australia

THE major problems in coastal engineering originate from the mobility of sediment on the ocean floor in the vicinity of coastlines. Recent attempts at tracing this movement have involved the use of radioactive isotopes. These are costly, can be a hazard to health and generally suffer from a short life for tracking purposes. Unless material can be identified for at least twelve months, the net motion cannot be accurately ascertained.

Another approach appears simpler and more rewarding. It is based on the premise that the major features of a coastline emanate from centuries of interaction between geological and climatic factors. Of the former, wave action is the most important, particularly the action of swell, although storm sequences play their part by putting the sediment continually back into circulation. But in the end the predominant swell will give the coastline its particular outline, the recognition of which can help define the direction of the net sediment movement.

Model Tests

Tests have been carried out at the University of Western Australia to determine this equilibrium shape for some persistent swell direction. In a scaled model of a typical coastline, waves were generated at an angle of 45° towards a straight length of sandy beach in which were included three concrete sections resembling rocky headlands. Up-coast of the two beach units so formed, no sand replenishment occurred, and the coast was allowed to erode. Material was removed beyond the down-coast rock outcrop so as not to interfere with the natural shaping of the coastline.

The depth of the water in the model was constant at 7 in. and the beach was built up flat 3 in. above this level, with 20 ft. distance between headlands. No scale can be attached to the study as no prototype conditions existed for it; but if an undistorted scale of 1:60 were to be placed on the previous dimensions, the waves generated would have represented prototype waves of 10-sec. period and 5-ft. height approximately.

The waves were generated for intervals of several hours, after which a survey was made of the water-line and the underwater depths. This was continued until a quasi-permanent shape resulted in the up-coast unit, which occurred when any wave broke simultaneously around the length of the bay so formed. Fig. 1 shows the progressive stages in the beach-line of the two tests carried out. Fig. 2 shows the underwater contours at the end of each test.

The conclusions that may be drawn from these figures are:

(a) The equilibrium shape for a sedimentary coastline with oblique swell is that of a half-heart with the curved portion up-coast and the tangent section down-coast of the bay unit. Although the final shapes obtained in the up-coast bays of the model tests only approximated to this, it can be reasoned that with intermittent storm waves and slight alterations in wave directions the beach-lines would have been smoothed out. (It is intended to conduct such tests in the future.) The straight section should be almost parallel to the crests of the waves in deep water as they are refracted very little, whereas the curved portion of the bay is sculptured by the waves which are diffracted around the up-coast headland and refracted inside the bay.

(b) The shape of the down-coast bay at any time is dictated by sediment passing to it from the up-coast bay. In Fig. 1 the former is more eroded in Test No. 1 than Test No. 2 because less material has been removed from the up-coast unit. It can be seen how the supply of sediment to the down-coast bay will vary continuously throughout the full development of the up-coast bay.

(c) From the underwater contours of Fig. 2, it is seen that a circular current has developed which has caused a shoal near the tangent point. In Nature this is not likely to be so pronounced because of the intermittent nature of the wave occurrence and the influence of storm sequences. It is this circulation that has helped cause the irregular shape of the model coastlines, because the bottom contours influence the refraction pattern of the waves.

But the principal deduction is that, given a persistent swell from an oblique direction moving sediment down-coast, an erosive situation will cause bays of the half-heart shape to be fashioned between the headlands. Equally, the occurrence of such bays will indicate the net movement of sediment and the direction of the persistent swell.

Fig. 2. Underwater contours in the model when the up-coast bay was in quasi-equilibrium. Accreting effect of the groyne and breakwater is shown dotted

Equilibrium Shape In Nature

To check the validity of this contention in Nature, a section of the South African coast has been chosen where a predominant wave direction is known to exist^{1,2}. An outline of the coast is sketched in Fig. 3. As indicated, the persistent swell is from the south-west, and the bays have taken the half-heart form of which the tangent section tends to be normal to the wave direction. The shape of the continent would preclude much movement of sediment eastward around Cape Agulhas, and hence erosion has occurred along this section of coast over the centuries and is probably still doing so. Notwithstanding any seasonal or other reversals, the net or long-term movement of sediment is towards the east.

With the acceptance of conditions producing the equilibrium shapes of coastline, it is possible to produce a map showing the net sediment transport around the coastlines of the world. I am at present undertaking this, checking areas with less-pronounced features by referring to any ocean-swell charts which are available.

Stabilization of a Coast

Although reversals of drift can cause problems of erosion and silting in man-made coastal structures, the major difficulties arise from the long-term movement in one direction. Attempts at reducing or prohibiting this motion of sediment, generally by means of groynes, have met with varied success.

Referring to Fig. 2, it is apparent that if groynes are constructed between B and C they are equivalent to extending the headland out to sea and, assuming that there is still some longshore movement, the shoreline will advance

by accretion to the new line shown dotted. The groyne here has accomplished its purpose. On the other hand, groynes built in an area AB, if it is still subject to erosion, will be ineffective. Should the bay be almost stable, groynes built there might sustain the coastline against seasonal fluctuations, although it has been shown elsewhere how groynes can accelerate erosion³. A more effective means of building up the coast between A and B is to extend the headland at A by means of a breakwater or other structure. The waves then have a new centre of diffraction and will effect a new shape as indicated.

On a coastline where there is substantial net movement of sediment, the best means of reducing it, or preventing it altogether, is to construct headlands about which the stable half-heart bays may form. The distances between these headlands should be of the order of miles, so that a wide expanse of

Fig. 3. Section of the South African coast where a south-westerly swell is predominant. Areas dotted indicate sandy shorelines as recorded in Admiralty Charts Nos 2283, 4 and 5

Fig. 4. (A) A method of preventing long-term movement of sediment along the coast, showing allowances for erosion and accretion. (B) A step method of approaching the stable half-heart shape by means of a movable offshore breakwater

ocean floor is affected. Allowance will therefore have to be made for erosion of some coastal areas and accretion in others is illustrated in Fig. 4A.

Because of the magnitude of structures required (to be effective in the first instance at the initially large distances offshore), a step procedure seems advisable. For example, a floating offshore breakwater sunk near the coast would cause a tombolo to form, after which a certain quantity of sand would accumulate. The breakwater could then be refloated and moved seawards. This process would need to be continued until the equilibrium shape was obtained as shown in Fig. 4B.

With such stable bays no sea defence works would be necessary, because a sedimentary coast can pro-

vide a defence which is far superior to any sea walls or revetments devised by man. But to allow for storm-cycles and the short-term reversals of drift, a sufficient width of beach should be allowed as working capital on which the sea can operate. Once the coast has been stabilized, by preventing the net movement of sediment, no long-term erosion need be anticipated and the 'active' beach width can be minimized.

RADIATION-INDUCED IONIC REACTIONS: THE RETARDATION OF THE HOMOPOLYMERIZATIONS OF α -METHYL STYRENE AND β -PINENE BY WATER

By T. H. BATES, J. V. F. BEST and T. FFRANCON WILLIAMS

Chemistry Division, Atomic Energy Research Establishment, Harwell

EVIDENCE has been presented^{1,2} that the polymerization of isobutene initiated by ionizing radiation is a liquid-phase ionic reaction. It is also stated¹ that high polymer is formed by irradiation of α -methyl styrene at low temperatures, although no experimental results are quoted. As both isobutene and α -methyl styrene are examples of monomers that do not readily polymerize by radical mechanisms³, it is to be expected that their facile homopolymerization would be favoured by an ionic mechanism. Nevertheless some recent communications^{3,4} describe the γ -ray polymerization of α -methyl styrene as a radical process, and since the reported inhibitory effects of oxygen and benzoquinone on the radiation-induced polymerization of isobutene are equivocal with respect to either radical or ionic mechanisms, we wish to report new evidence in favour of the ionic polymerization of α -methyl styrene and β -pinene carried out *in vacuo* at the ambient temperature, about 30° C., of a cobalt-60 γ -ray source. Both these latter monomers were found to undergo a high degree of conversion to polymer without the marked reduction in rate as a function of amount of conversion that was previously observed for isobutene¹. Again, in contrast to isobutene where the isolated polymer had an $\bar{M}_n$ exceeding 100,000 for less than 20 per cent conversion¹, the $\bar{M}_n$ values obtained for α -methyl styrene and β -pinene polymers in this investigation only correspond to about 15 monomer units in each case.

Our earliest experiments on β -pinene⁵ established that the polymer yield was sensitive to the pre-treatment of the monomer and particularly to the drying agent employed. Thus it was found that the drying of freshly distilled monomer over sodium, magnesium perchlorate, phosphorus pentoxide and calcium hydride in a large number of separate experiments all gave initial values for G (-monomer) of less than 50, whereas passage of the β -pinene over activated alumina and silica gel gave corresponding polymer

yields of 370 and 1,055 respectively. Further, the use of silica gel for drying the liquid within the vacuum apparatus gave the highest yields hitherto recorded for β -pinene, G (-monomer) exceeding 3,000 in some runs. The use of molecular sieve 4A (aluminium sodium silicate) as a drying agent for the vapour *in vacuo* gave corresponding G values around 400; but by this procedure the monomer suffered partial isomerization to α -pinene and camphene before irradiation. A confirmation that the polymer yield is affected by the efficacy of the drying agent and not by the removal of other impurities is provided by the effect of deliberately added water to β -pinene; in this instance a sample of water-saturated monomer gave polymer with only a G (-monomer) of 6.8.

A similar conclusion that water exerts a powerful retarding effect on the radiation-induced polymerization of α -methyl styrene is afforded by a comparison of yields obtained with monomer samples which had been first passed down silica gel and then either sealed *in vacuo* or else equilibrated with excess water in a vacuum line prior to seal-off. In the former case the G (-monomer) values measured with a dilatometer were of the order of 10,000 whereas the latter conditions gave an initial G value of about 10. Additional experiments in which concentrations of water below 0.02 weight per cent were added to samples during the course of polymerization showed a marked suppression of the original high rate.

The important role of water in these systems as a polymerization inhibitor cannot readily be explained in terms of the radical reactions (1) and (2):

Both these processes are endothermic in the forward direction, and the reverse of (1) is a facile reaction of OH radicals with organic compounds. In any event, these reactions would lead to chain transfer rather than the marked retardation which is observed.

There is no evidence that water acts as a chain transfer agent in radical polymerization in aqueous systems⁶. However, in terms of an ionic polymerization mechanism, it is apt to consider the possibility that reaction (3) represents the interaction of water with a propagating cationic centre.

For the comparable reaction represented by (4):

it can be calculated that in the gas phase ($n = 1$) it represents an endothermic process by 27 k.cal./mole. Nevertheless, if the hydronium ion H_3O^+ is fully solvated by surrounding water molecules, reaction (4) becomes exothermic by virtue of the heat of solution of H_3O^+ , which amounts⁷ to more than 100 k.cal./mole. Franklin⁸ has calculated that the forward reaction (4) is 21 k.cal./mole exothermic when all the reacting species are solvated in dilute aqueous solution; by consideration of both heat and entropy changes it was also deduced⁸ that the ratio of rate constants for the forward to the reverse reaction (4), at 25° C., is 1.1×10^{15} . Also Evans and Halpern⁹ have measured a similar activation energy of 22.6 k.cal./mole for the acid-catalysed addition of methanol to α -methyl styrene which involves a rate-determining step analogous to the reverse of (4) except for the replacement of water by methanol in the reaction. Thus this evidence suggests that the acid-base equilibrium in reactions akin to (3) and (4) in hydroxylic media lies well over to the right-hand side of the equation. Another exothermic process representing the interaction of a carbonium ion with water⁸ is illustrated by (5) and represents the familiar fast solvolysis reaction of carbonium ions in aqueous media:

Similar calculations to those for (4) show⁸ that reaction (5) is again highly favoured in the forward direction. We therefore surmise that the theoretical validity of reactions (3) and (5) for the removal of carbonium ions rests on the degree of solvation of the hydronium ion formed.

In a solvent of low dielectric constant it is likely that ions only maintain their existence as ion-pairs. The overall act of radiolysis to form a suitable ion-pair can be represented by (6) where the products consist of a carbonium ion and an allylic carbanion:

In the case of β -pinene the carbonium and carbanion centres may be located in a rearranged molecule⁵. The path of formation of the ions in (6) could involve the reaction of the parent ion with an olefin molecule to form the carbonium ion and an allylic radical^{10,11}, followed by electron capture by the latter.

According to this postulate, polymerization proceeds because of stabilized ion-pairs which allow the positive ion a sufficient lifetime to engage in many addition and transfer (to monomer) steps before eventual neutralization by the counter-ion. The presence of water in such a non-polar medium would lead to strong dipole association, whereby dispersed water molecules would be rapidly attracted by electrostatic forces to the vicinity of an ion-pair in a time which has been estimated by Ingold¹² to be less than 10^{-6} sec.; this period is of the same order as the estimated interval between successive propagation steps in the cationic polymerization of isobutene³. When sufficient water molecules are present in the solvation sheath of the ion-pair, reactions (3) and (5) provide a path for the removal of the positive propagating ion and its replacement by a solvated hydronium ion, thus quenching the polymerization.

In conventional ionic polymerization induced by Friedel-Crafts catalysts, traces of water often function as a necessary co-catalyst to form the initiating complex¹³, but there is evidence that further increase in water concentration can lead to a reduction in polymerization-rate¹⁴.

The practical importance of this effect of water in the radiation chemistry of olefins is that latent processes may not be fully realized unless the most rigorous drying of solvents is employed. Divergent yields have been reported by different workers^{1,8} for the polymerization of isobutene at -78°C ; since enhanced yields were obtained in this system¹⁵ by the addition of solid powders such as silica gel and zinc oxide, these latter results may well be attributable to the dehydrating effect of such additives. In other work on the homopolymerization of α -methyl styrene, the recorded rates of polymer formation per 10^6 rads have ranged from 0.01 per cent conversion³ to values between 0.7 and 5.0 per cent⁴. At the same temperature (30°C) and with comparable dose-rates we have observed considerably greater yields amounting to more than 10 per cent conversion per 10^6 rads; even such yields may in truth be only limiting values, since a finite concentration of water must persist under the driest conditions hitherto employed.

A PROBABLE FREE-RADICAL MECHANISM FOR SYMBIOTIC NITROGEN FIXATION

By DR. NORMAN BAUER

Chemistry Department, Utah State University, Logan

SOME recent very significant experimental data on the evolution and isotopic exchange of hydrogen from nitrogen-fixing root nodules, obtained by Hoch, Schneider and Burris¹, serve to illuminate various possible reaction mechanisms of biological nitrogen fixation. Recent theoretical work² on the properties of aqueous nitrogen and current experimental work³⁻⁵ on the physical-chemical properties of certain haem proteins ('legoglobins'⁴, *Lb*, rather than 'leghaemoglobin') associated⁶⁻⁸ with symbiotic nitrogen fixation, when combined with the information provided by Hoch, Schneider and Burris, has brought to mind a new relatively simple set of hypotheses concerning the first several steps of symbiotic nitrogen fixation. Many of the previous ideas on this subject have been discussed and developed by Roberts⁹. The central hypothesis in the present quite different approach involves formation of the as yet unobserved but thermodynamically predicted³ free radical N_2H . In conjunction with ideas and facts³ about the affinity of legoglobins for nitrogen and other simple gases, and knowing⁴ that the oxidation potential of iron in ferroleoglobin is extraordinarily great, the hypothesis of N_2H formation accounts for a diversity of phenomena which is otherwise not understandable at present, as shown below.

Since about 1 per cent of the secondary^{3,4} (. . .) haem sites on hydrated ferroleoglobin, $LbFe^{+2}OH \dots$

(or on oxygenated $LbFe^{+2}O_2 \dots$), are known³ to be occupied by nitrogen at 293° K. and 1 atm., it is probable that the first step is:

or, in aerobic regions of the nodule:

or, on some 'hydroperoxyl sites' produced through the electron affinity of oxygen and subsequent reactions:

An initial step (1d) like (1c) except with Fe^{+3} instead of Fe^{+2} is also possible. Because of the noble-gas character of nitrogen, no other possibilities for 'sorption' of nitrogen at room temperature and pressure than reactions of type (1a-1d) are presently evident; and it will be shown below that nitrogen must be bound to some other molecule in order that certain fixation reactions can occur. The standard free energy changes for (1a-1d) are about +2.4 k.cal./mole³. Considering the high concentration of *Lb* in nodules^{4,7}, this allows a relatively great molar concentration of sites occupied by nitrogen, compared with many enzyme-substrate systems, in spite of the fact that the sites are far from saturated.

A thermodynamically feasible second step is the production of atomic hydrogen, or the somewhat equivalent hydroperoxyl radical water, at the site of nitrogen attachment. This follows from knowing⁶ that, at least for one *Lb* species, the oxidation potential for $LbFe^{+2} \rightarrow LbFe^{+3} + e^-$ at pH 5.7 is +30 mV. relative to the standard hydrogen electrode and that this potential has the very large pH dependence $dE'_{ox}/d(pH) = +126 \text{ mV./pH}$. That is, in a certain range of low pH, ferroleoglobin itself without any other substrate than the usual hydronium ions in the environment of the protein must be able to liberate appreciable concentrations of hydrogen. For example, at $pH_{Lb} = 5.7$ the free energy change for $LbFe^{+2} + H^+ \rightarrow LbFe^{+3} + 1/2H_2$ is -690 cal./mole when (H^+) and (H_2) are at unit activity; at $pH_{Lb} = 5.0$ but likewise with $a_{H^+} = 1$, $a_{H_2} = 1$, the corresponding free-energy change is -2720 cal./mole. This means that at equilibrium, $P_{H_2} = 4.4 \times 10^{-7} \text{ atm.}$ for $pH = 5.7$, and $P_{H_2} = 1.15 \times 10^{-3} \text{ atm.}$ for $pH = 5.0$, when the activity ratio $\rho = (LbFe^{+2})/(LbFe^{+3})$ is assumed to be 1.0×10^{-3} . If all but 0.5 per cent of the *Lb* is maintained in the reduced state by reactions in the nodule ($\rho = 5 \times 10^{-3}$) then for $pH = 5.0$ the P_{H_2} can reach the relatively high value of 0.04₆ atm., comparable to what was found by Hoch, Schneider and Burris some 300 min. after nodule excision. This range of pH values is about one unit lower than the gross average values found⁶ in soybean roots and nodules; but lower values in *Lb*-containing micro-regions of the nodule would be consistent with the strongly acid groups that are associated with the quite low isoelectric point of legoglobins ($pH \ 4.4-4.7$)¹⁰. It should be recalled^{4,7} that *Lb* exists in rather high concentrations in root nodules.

Not only does the above analysis account for the observed hydrogen production so far as equilibrium may be concerned; but it also implies the intermediate production of H radicals or their equivalent, in harmony with current ideas about the mechanism of hydrogen liberation from electrodes or polyelectrodes. Thus we expect:

or, in aerobic regions:

Note that hydrogen atoms would be produced at the same site that promotes nitrogen attachment, a situation very favourable kinetically for a reaction between nitrogen and hydrogen atoms, even though at equilibrium the hydrogen atom concentration must be very small relative to hydrogen. Furthermore, even in the presence of some oxygen a high reductive potential can be maintained by *Lb*, accord-

ing to the results of George and Stratmann¹¹ for the quite similar myoglobin.

The third step would then be a direct or indirect combination of nitrogen and hydrogen atom, the simplest being:

In equation (3) $Lb.N_2$ represents any one of the three complexes produced in (1a), (1b) or (1c). The reason for emphasizing the existence of a complex in equation (3) is to bring out the fact that a free radical and a molecule may not combine without some means of dissipating the binding energy; in this case the known forces³ exerted by the h  m protein on nitrogen ('secondary gasation') can serve such an essential purpose. It has already been shown² that the standard reaction for $N_2 + H_2 \rightarrow N_2H$ would be spontaneous; and that a standard free energy investment of 32 k.cal./mole would be required to break the N_2-H bond. Furthermore, as reaction (3) proceeds it would have to shift equilibrium (2a) and lead to the appearance of (oxidized) ferrilegoglobin, which is what Hamilton, Shug and Wilson¹² found in reduced nodule extracts when helium was replaced by nitrogen. However, equilibrium (2a) must be maintained with a preponderance of Lb in the ferrous form for an appreciable yield of hydrogen. This is in harmony with the observations of Keilin and Smith⁷ that at all stages of nodule development no ferrih  m proteins were observed ($p < 10^{-3}$). In order to maintain such a favourable reduction potential at the iron site, some coupling of legoglobin with an electron transport system is required; and such a coupling is likely according to Falk, Appleby and Porra¹³. Also, an essential link in such an electron transport system having a one-electron transfer at one end is very probably a molybdoflavoprotein¹⁴, especially since molybdenum is a specific requirement for nitrogen fixation. Nevertheless, a molybdenum reduction site would not be adequate for nitrogen fixation even though its reduction potential for hydrogen atom formation were more favourable than that of an $LbFe^{+2}$ site, because the concentration of molybdenum in the nodule is too small to furnish an adequate number of sorption sites for the weakly bound nitrogen.

Subsequent steps for the successive addition of hydrogen atoms to N_2H_n are obvious and thermodynamically feasible², leading to the eventual production of hydrazine, in harmony with the elegant nitrogen-15 tracer experiments of Bach¹⁵. However, alternative pathways including even oxidative steps⁹ may develop at this or even earlier stages owing in part to the possibility² of a direct succession of electron, proton captures by N_2H_n . Of course, once N_2H has been formed, the subsequent reduction to $2NH_3$ follows easily through conventional reactions or perhaps through a hydrazine reductase, such as a molybdoflavoprotein. The present view is thus consistent with the idea stressed by P. W. Wilson and R. H. Burris¹⁴ that NH_3 is the 'key intermediate' between inorganic and organic nitrogen.

Innumerable side or parallel reactions will undoubtedly develop as soon as N_2H is produced, especially under aerobic conditions. Only two of these need be considered here, to illuminate the possible need⁹ for a reinterpretation of the usual Michaelis-Menten constant of the symbiotic nitrogen-fixing process. The back-reactions:

or

are thermodynamically feasible², and imply rate laws second order with respect to N_2H , meaning that as N_2H production increased, that is, as occupation of active sites by nitrogen increased, a point would be reached where the back reactions would cut down drastically on the increase in net fixation-rate with increasing P_{N_2} , otherwise expected when the reactive sites are not saturated. Thus the apparent fact that the ' N_2 -fixing complex in nodules is half-saturated at a P_{N_2} of about 0.025 atm.¹¹' may actually reflect, in part, the effect of back reactions (4a) and (4b) going on at a considerable rate. This consideration helps one to understand how the N_2 -fixation rate is not appreciably enhanced above $P_{N_2} \approx 0.05$ atm., even though only about 1 per cent of the total h  m sites of all kinds are occupied. Further consideration shows, however, that of these the hydroperoxyl site, probably the most active type, must be almost fully saturated at $P_{N_2} = 1$ atm. if the effect of hydrogen, of nitrogen and of the binding of $O_2 \cdot H \cdot$, N_2 are taken into account.

The above hypotheses explain a number of striking facts about symbiotic nitrogen fixation, some of which are discussed briefly below:

(1) *N_2 -nitrogen inhibits hydrogen evolution*¹. The formation of N_2H would divert hydrogen atoms from their normal fate of eventually combining, in association with some third body, for example, protein, to form hydrogen molecules.

(2) *N_2 -nitrogen is essential for promoting an appreciable exchange reaction between deuterium and endogenous hydrogen*¹. The presence of free N_2H would allow the exchange $N_2H + D_2 \rightarrow N_2HD + D$, among others, because the relatively weak binding free energy between nitrogen and hydrogen atoms (32 k.cal./mole) implies that the H in N_2H is relatively free to act as a kind of quasi H-atom; and $H + D_2 \rightarrow HD + D$ is known¹⁶ to occur readily even in the low-temperature range of $+10^\circ$ to 100° C.

(3) *H_2 -hydrogen inhibits the evolution of hydrogen, itself*. From the present point of view, the evolution of hydrogen would probably depend on two slow processes in series: (A) Production of hydrogen atoms from $LbFe^{+2}$; and (B) conversion of the hydrogen atom to the molecule, either by (a) a very slow process of two hydrogen atom migrations or attachments to the same third-body site, analogous to the probable mechanism giving rise to hydrogen over-voltages on electrodes, and/or (b) a more rapid process near the reactive site such as $Lb-H_n + H \rightarrow Lb-H_{n+1} + H_2$, a type common to free radical reactions. Recent preliminary work in this laboratory⁶ indicates that nodules treated with hydrogen slowly yield a different, more stable, type of ferri-legoglobin ($LbFe^{+3}$)_H, than that extracted under argon ($LbFe^{+3}$)_A or under air ($LbFe^{+3}$)_a. The ($LbFe^{+3}$)_H had an oxidation potential smaller than that of ($LbFe^{+3}$)_a by about 40 MV.; and at 30° C. the ($LbFe^{+3}O_2$)_H auto-oxidized to ($LbFe^{+3}O_2$)_H, only about one-half as fast as fresh ($LbFe^{+3}O_2$)_A. Also, in the potentiometric titration of $LbFe^{+3}$ with phthiocol, several equivalents of h  m-protein side-groups, as well as iron, were easily reducible. Hence I tentatively conclude that hydrogen molecules will convert $LbFe^{+2}$ to a less-reactive form which will at

least slow down step (A) above; and possibly alter the rate of step (B) as well. This would mean that the intrinsic evolution of hydrogen, itself a possibly unavoidable by-product of the step that produces the essential hydrogen atoms, may eventually lead to a substantial reduction of nodule effectiveness.

(4) *H₂-hydrogen is a specific competitive inhibitor of N₂-fixation.* (A) Hydrogen is known³ to attach itself to legoglobin, with a standard uptake free energy of about +2.3 k.cal./mole, in a way quite similar to that of nitrogen. If hydroperoxyl sites were the most active type, even though the least abundant, the fixation-rate in the absence of hydrogen would be characteristic of secondary sites nearly saturated with nitrogen because of specific O₂..H..N₂ binding forces. In this case the rate would be decreased through displacement of nitrogen by hydrogen. (B) The conversion of LbFe²⁺ to a hydrogenated form that produces atomic hydrogen at a lower rate, evidence for which is given in (3), must also result in a decrease in N₂H formation, that is, in rate of nitrogen fixation. (C) To some extent molecular hydrogen would also compete for the bound HO₂ radicals, analogous to the competition for OH radicals postulated by Pethica, Roberts and Winter¹⁷, but this must be a second-order effect in view of the slow molecular deuterium exchange-rate in the absence of nitrogen.

(5) *Carbon monoxide inhibits nitrogen fixation but is not primarily a competitive inhibitor.* (A) The known attachment of carbon monoxide to legoglobin, forming LbFe²⁺CO..., would not destroy the secondary sites for nitrogen attachment^{3,4} except at extreme carbon monoxide pressures, though it would alter (probably lower) the oxidation potential of LbFe²⁺; (B) The principal effect of carbon monoxide should be to divert hydrogen atoms away from N₂H formation, according to the known¹⁶ complicated reactions: H + CO + M → HCO, followed by a set of reactions producing formaldehyde, glyoxal and polymers; and possibly by another parallel set regenerating atomic and molecular hydrogen.

(6) *Carbon monoxide strongly inhibits exchange of endogenous hydrogen with deuterium.* The reactions in (5) (B) incorporate hydrogen atoms into compounds much more stable than N₂H, hence are much less likely to furnish exchangeable quasi hydrogen atoms. This implies that those reactions which might regenerate atomic and molecular hydrogen from HCO in the gaseous state are not appreciable under conditions prevailing in the nodule.

(7) *O₂-oxygen is a requirement for symbiotic nitrogen fixation, but there is some inhibition by oxygen at high pressures.* Hydroperoxyl sites on ferroleoglobin (equation (1c)) are probably the most active though the least abundant type; and also should be nearly saturated by nitrogen at 0.1 atm. This follows from the presence of a loosely bound atomic hydrogen on the hydroperoxyl site adjacent to the secondary site; and from the known affinity between atomic hydrogen and nitrogen. Also, the standard free energy for the change N₂ + HO₂ → N₂H + O₂ is probably² of the order of only a few k.cal./mole but negative. At high values of P_{O₂}, the secondary sites could just as well be occupied by oxygen as by nitrogen (that is, by molecules of similar size, shape and polarizability), according to the theory of secondary gasation^{3,4}. Of course, the above considerations are not complete or necessarily definitive because of the influence of oxygen on bacterial metabolism.

It must be emphasized that some of the properties of legoglobin referred to in the present discussion may not represent the exact behaviour of the native material within the intact nodule. This is underlined by the fact that legoglobin oxidizes⁷ and auto-oxidizes⁵ rapidly when extracted aerobically, that it is susceptible to change in the presence of hydrogen and that it is sensitive to dialysis and changes of pH and ionic strength³. There can be little doubt that the properties of the native legoglobins must be known before the chemical processes in nitrogen-fixing nodules are understood, in accordance with Keilin's early ideas are in harmony with the recent work of Falk, Appleby and Porra¹³ showing a correlation between deficiencies of haem synthesis within the nodule and ineffectiveness of nodules in respect to nitrogen fixation.

It may be concluded that the present set of hypotheses provide a consistent way of viewing most of the central qualitative and semiquantitative aspects of symbiotic nitrogen fixation, excluding for the time being the more difficult questions about the magnitudes of the various rate constants. In view of the complexity of interrelated facts that must be explained, it is difficult at this stage to see an alternative set of hypotheses that could differ radically from the present ones. It would appear worth while to look for the free radical intermediates suggested here, using the powerful high-resolution electron spin resonance techniques now available in some laboratories; but keeping in mind that the free radical spectrum of the expected water, atomic hydrogen, N₂H_n and Lb intermediates as a function of time will undoubtedly be most complex. The liberation of molecular hydrogen from aqueous legoglobin and the detection of hydrogen atom radicals in that process would also be an important test of the present hypotheses. Eventually, of course, it should be possible to find conditions for the fixation of nitrogen through the mediation of a protein molecule having properties at least very similar to those of the legoglobins.

I am grateful for support from the Herman Frasch Foundation and the Utah Agricultural Experiment Station in this work.

INTERACTION ('PERIPOLESIS') OF MACROPHAGES AND LYMPHOCYTES AFTER SKIN HOMOGRAFTING OR CHALLENGE WITH SOLUBLE ANTIGENS

By J. A. SHARP and R. G. BURWELL

Department of Anatomy, University of Leeds

IN conjunction with an investigation of the lymphoid reactivity to tissue homografts¹, we have recently examined the behaviour of living cells in cultures of lymphoid tissue taken from rabbits which either had received skin homografts or had been challenged with an intravenous soluble antigen.

The explants of lymphoid tissue were set up in a simple culture chamber² in plasma clot, with a fluid medium composed of equal parts of human serum and a chemically defined medium³. The activity of the cells, and especially of the macrophages and lymphocytes, in the outgrowth from these explants was recorded on 16-mm. film by time-lapse phase-contrast cinemicrography, at 12 pictures per min.

In the initial experiments homografts of skin 2 cm. in diameter were applied to the ventral aspect of the ears, 1-2 cm. from the external auditory meatus, in thirteen young adult male rabbits. Eight to ten days later the first regional (parotid) lymph node draining the area of the graft was removed aseptically. Since it was known that the upper half of the node was more likely to have received lymph from the grafted area and to contain the reactive cortex¹, tissue from this region was taken for culturing. A total of about 120 explants from these lymph nodes were cultured. The effect of a soluble antigen has also been examined by challenging seven rabbits with a single intravenous injection of 5 ml. of horse serum. Three to twelve days later the spleens were removed for culture; a total of about 150 explants were obtained from the seven animals. Control cultures were provided by about 100 explants of spleen from five normal rabbits which had not been exposed to the antigen.

When the cine film of the cultures of the antigenically challenged lymph nodes and spleens was studied, an association was noticed between some of the macrophages and small lymphocytes. The association consisted of the movement of lymphocytes close to the surface of particular macrophages. The cells concerned showed their normal motility during the association, the macrophages moving slowly and at random, while the contiguous lymphocytes continued to move relatively rapidly around the edge and over the upper free surface of the macrophage. This association was seen to persist for prolonged periods; during most of this time

the contact between lymphocytes and macrophages appeared to be of a surface-to-surface nature, although the more rapidly moving lymphocytes would at times move away, only to return again to the macrophage.

Prolonged contacts of this nature were not seen in the control cultures of spleen. Though random contacts between macrophages and lymphocytes occurred quite frequently, such contacts never persisted for more than a few minutes.

Figs. 1-4 are enlargements from the original 16-mm. film. In Fig. 1 the arrow indicates a small lymphocyte in close association with the macrophage immediately above, in a culture of lymph node which had drained a homograft of skin. Fig. 2 shows the same two cells, still in contiguity, about 5 hr. later. Figs. 3 and 4 illustrate a similar association between a group of lymphocytes and a macrophage in an explant of spleen which had been challenged intravenously with horse serum. The lymphocytes are so closely packed that they largely obscure the macrophage which is only partially visible. The time-interval between Figs. 3 and 4 is approximately 75 min.

An association between normal small lymphocytes and cells in mitosis, megakaryocytes and malignant cells, has been recorded by Pulvertaft and his colleagues^{4,5}. They examined explants of normal and pathological human lymph nodes and bone marrow *in vitro* using time-lapse phase-contrast cinemicro-

Fig. 1. (1) Cells in the outgrowth from an explant of lymph node which had drained a homograft of skin. Two days *in vitro*. (2) The same cells 5 hr. later. (3) A group of lymphocytes surrounding and partially obscuring a macrophage. Explant of spleen from rabbit injected intravenously with 5 ml. horse serum. Two days *in vitro*. (4) The same field 75 min. later

graphy, and, in many instances, observed the entry of normal small lymphocytes into the cytoplasm of living malignant cells. The cytoplasmic invasion of epithelia, fibroblasts, endothelial cells and ova by small lymphocytes is now firmly established⁶. For these phenomena wherein lymphocytes become adherent to other cells or apparently pass over or into them, Pulvertaft and his colleagues have suggested the name 'emperipolesis' from the Greek 'εμπεριπολής'—'inside round about wandering'.

The interaction between normal small lymphocytes and macrophages has not been recorded previously, but an association between 'malignant' lymphocytes and macrophages has been shown to occur in tissue obtained from humans with reticulososes⁵ and from mice with certain lymphocytic tumours⁷.

In our experiments there was no evidence of the entry of small lymphocytes into the cytoplasm of the macrophages. We suggest, therefore, that to this phenomenon of free lymphocytic movement around the perimeter of a cell for hours at a time but without entry into its cytoplasm, the name 'peripolesis' be applied.

The significance of peripolesis is by no means clear. The pattern of our experiments and the results observed would suggest that the phenomenon might be related to the early (radio-sensitive) phase of antibody production. It seems improbable that the foreign human proteins present in the culture medium could be involved in the cellular interaction, as peripolesis was not observed in the control cultures. It might be that the lymphocytes are transferring nutritive substances⁸ necessary for antibody production to the macrophages. An antigen-antibody attraction, which might be the explanation of the association which Nossal⁹ observed between *Salmonella adelaide* and sensitized plasma cells, cannot be excluded as an explanation of peripolesis. The final possibility exists that the macrophages, having taken up antigen from the extra-cellular fluid *in*

*vivo*¹⁰, are in the process of supplying an antigen-complex to the lymphocytes which then stimulates antibody production.

Though it is now established that the plasma cell series synthesizes antibodies^{10,11}, other workers have suggested that the stem cell of antibody production may be the macrophage^{10,13}, primitive reticular (mesenchymal) cell¹² or lymphocyte¹³. Our observations are consistent with those of Roberts *et al.*¹³, who showed that subcutaneous or intramuscular injections of cell suspensions containing both macrophages and lymphocytes into X-irradiated immunologically inert rabbits would result in the transformation of these cells, after antigenic challenge, into large pyroninophilic antibody-producing cells.

The suggestion¹⁰ that the macrophages may provide the first link in a chain leading to antibody production would explain the prolongation of skin homograft survival after injection of trypan blue¹⁴, by temporarily impairing the capacity of macrophages to take up antigen derived from the graft.

The phenomenon of peripolesis in antigenically challenged animals is being investigated at the present time and will form the basis of a communication in the near future.

VISUAL PIGMENT FROM A PURE-CONE RETINA

By DR. H. J. A. DARTNALL

Visual Research Division, Ophthalmological Research Unit (M.R.C.),
Institute of Ophthalmology, London

ONLY one of the numerous visual pigments that have been extracted to date from the retinae of vertebrates has any claim to be regarded as a cone pigment¹. This is iodopsin², discovered by Wald in 1937 in the chicken retina. Extracts of chicken retinae contain a mixture of photosensitive pigments: iodopsin with $\lambda_{\text{max.}} = 562 \text{ m}\mu$ and a rhodopsin with $\lambda_{\text{max.}} =$ about $500 \text{ m}\mu$. Since the rhodopsins are known to occur in some pure-rod retinae, and since the chicken retina is rich in cones as well as rods, it has been assumed that the chicken pigments are not mixed *in vivo* but exist separately, the rhodopsin being in the rods and the iodopsin in the cones.

According to the Duplicity Theory, scotopic vision is mediated by rods, and photopic vision by cones. Consequently, the fact that the scotopic and photopic visual functions of the chicken, as measured by Honigsmann³, roughly correspond to the absorption spectra of chicken rhodopsin and iodopsin also sup-

ports the view that these pigments occur in the rod and cones respectively.

These arguments for believing iodopsin to be a cone pigment, though practically compelling, are nevertheless indirect. Until it becomes possible to divide rods from cones and to extract them separately, some doubt remains. Such doubt, which may seem trifling in the case of iodopsin, can be a serious obstacle to interpretation in other instances⁴ where extraction of a mixed rod-cone retina likewise yields a mixture of photosensitive pigments but where (unlike the chicken) no sensitivity functions have been measured to provide a guide in allocating the pigments.

In some species of nocturnal animals, the retinae are of the pure-rod type. In such cases any extractable visual pigment can be confidently assumed to be a rod pigment. Even when a few cones are also present in an otherwise pure-rod retina (for example, rat), this is still held to be a safe assumption, for it is commonly

supposed that the amount of cone pigment is small in comparison with the amount of rod pigment.

Conversely, in those diurnal species which have pure-cone retinae one could assume that any extracted visual pigment is a cone pigment. Unfortunately, there are not many species which possess such retinae, and all attempts to obtain visual pigment from them have so far proved unsuccessful¹. Among the well-authenticated cases of a pure-cone retina is that of the grey squirrel (*Sciurus carolinensis leucotis*)². This article briefly describes a recent successful attempt to extract visual pigment from it.

Extraction of the Squirrel Retinal Pigment

In August 1959, a batch of 40 grey squirrels was received. Between that date and February 1960, several retinal extracts were prepared, the procedures used being varied slightly in order to determine the best conditions for obtaining the visual pigment. The squirrels were fed throughout on standard 41B diet with occasional carrot and cabbage. For the first six weeks they also had mixed cereal. The animals thrived on this diet, and the last representatives of the batch weighed about twice as much as when they were first received.

The best extraction procedure found so far is given in the following account of one of the final experiments. Nine squirrels, of total weight 5.9 kgm., were dark-adapted overnight (17 hr.). All subsequent operations were also conducted in the dark room with the aid of a deep red safe-light. The squirrels were first anaesthetized by chloroform. Each animal was then killed by an intraperitoneal injection of nembutal. The eyes were removed and washed in water. Peripheral incisions at about the level of the ora serrata were next made in each eye. The front of the eye, including the lens, could then be lifted away leaving the posterior hemisphere (which contained the retina) full of vitreous humour. The next step was to slide forceps under the retina (which was quite loose) and to grasp it firmly at its junction with the optic nerve. The retina, lying across the limbs of the forceps, was then gently pulled away whole with its vitreous, and placed in McIlvaine's pH 7 buffer solution. With gentle shaking, the rather adherent vitreous separated from the retinae, so that by subsequent centrifuging they were precipitated, leaving blobs of vitreous floating in the supernatant buffer solution. This was removed. Sucrose solution (40 per cent) was then added to the retinae, and the mixture vigorously shaken. This caused the outer segments of the visual cells (cones) to break away from the retinae. On centrifuging the mixture, the heavier retinal debris was precipitated to the bottom of the tubes, leaving a slightly cloudy supernatant suspension of visual cells in the sucrose solution³. This was pipetted off. A further yield was obtained by shaking the retinal residues a second time with sucrose solution, and repeating the procedure.

The visual cells were precipitated by diluting the suspensions with three volumes of McIlvaine's pH 4.6 buffer, and centrifuging them for 35 min. at 4,000 r.p.m. The clear supernatants were then pipetted off, leaving behind compact sediments of visual cells. These were bulked into a single tube with the aid of 4 ml. of pH 4.6 buffer (removed after further centrifuging). The combined outer limbs were then extracted with 0.5 ml. of 3 per cent digitonin for 1 hr., after which time the mixture was centrifuged and the clear extract withdrawn and made alkaline by the addition of 0.05 ml. of saturated sodium borate solu-

Fig. 1. Density spectra of the first and second extracts of squirrel visual cells before (A) and after (B) total bleaching. The outward measurements from 380 mμ to 620 mμ are given by the open circles; the return intervening measurements, by the black circles. Measurements were made at 35.5° C. on the first extract (at lower temperatures the extract became reversibly cloudy), and at 20° C. on the second extract.

tion (first extract). Further extraction with another 0.5 ml. of the digitonin solution, this time for 25 hr., yielded a second extract which was made alkaline as before. The two extracts were a pale pink colour and faded to pale yellow on exposure to light. The spent cells were pure white. In order to obtain information on the total amount of visual pigment in the squirrel retina (see below), the retinal residues were likewise extracted twice with 0.5 ml. portions of 3 per cent digitonin. These extracts were naturally more contaminated and contained only a trace of visual pigment.

Nature of the Squirrel Retinal Pigment

The density spectra of the first and second extracts before and after complete bleaching by a 15-W. lamp are given by the curves in Fig. 1. From the shapes of these curves it is clear that, in spite of the washing procedures described above, blood pigment and other impurities were present, in addition to visual pigment. Because of this contamination (relatively less in the first than in the second extract) the maxima for the unbleached extracts—at 490 and 480 mμ respectively—lie at shorter wave-lengths than would otherwise have been the case.

By presenting the results in the form of a difference spectrum (curve for unbleached, minus curve for bleached extract) the contribution of stable impurities

is eliminated. Moreover, a difference spectrum for an alkaline extract normally has its maximum at a wavelength only slightly longer than that for the pure visual pigment. The difference spectrum for the squirrel pigment (second extract) is shown by the circles in Fig. 2. It has $\lambda_{\max} = 504 \text{ m}\mu$, and agrees closely with that found by Bridges⁷ under similar conditions for the hamster pigment (crosses). This latter is a 'rhodopsin', that is, a visual pigment based on retinene₁. Bridges gives the maximum for the pure hamster pigment at $502 \text{ m}\mu$, and we may conclude that the squirrel pigment must be very similar.

None of the extracts prepared in the present investigation was sufficiently dense to allow a useful analysis by the method of partial bleaching⁸; consequently, the homogeneity of the squirrel pigment could not be definitely established. All extracts, however, yielded difference spectra identical within experimental error with that shown in Fig. 2.

The fully bleached extracts showed an unexpectedly high absorption in the $450\text{--}550 \text{ m}\mu$ range (see Fig. 1). This high absorption cannot be ascribed to the Soret band, nor to unbleached visual pigment (since the extracts were exposed to light until no further changes took place). Consequently it must be due to a photoproduct. Some information on this may be obtained as follows. At wave-lengths longer than $500 \text{ m}\mu$, the contribution of impurities to the density spectrum of an unbleached extract is small. Consequently, with the aid of the visual pigment nomogram⁹ it is possible, from this spectral region, to obtain an estimate of the amount of pure visual pigment present. By subtracting the density spectrum appropriate to this amount from the 'unbleached' curve, a remainder is left which is the contribution of the impurities. If this same contribution is now subtracted from the curve for the bleached extract, we are left with the density spectrum for the pure photoproduct. When this is

done with the curves of Fig. 1, it is found that, in addition to a rising extinction towards the short-wave end of the spectrum, the pure photoproduct has a low maximum at about $480 \text{ m}\mu$. Thus the photoproduct of the squirrel pigment includes a $480\text{-m}\mu$ pigment as well as the normal retinene₁, or retinene₁-protein, typical of rhodopsins in solution.

The presence of a $480\text{-m}\mu$ pigment in the products of bleaching would tend to displace the difference spectrum towards longer wave-lengths. The amount of $480\text{-m}\mu$ pigment was small, however, and the displacement caused must be correspondingly slight. At the least we may say that the true maximum of the squirrel pigment must lie between $490 \text{ m}\mu$, the $\lambda_{\max}$ of the least-contaminated extract, and $504 \text{ m}\mu$, the $\lambda_{\max}$ of the difference spectrum.

Interpretation of *in vivo* Observations on the Squirrel Retinal Pigment

The retinal pigment of the grey squirrel has been studied by Weale¹⁰ using the method of fundus reflectometry. He measured the fundus reflexion spectrum before and after exposure of the living retina to bright white light. The changes caused by the exposure were interpreted as due to the bleaching of a visual pigment, characterized by a very sharp absorption band with maximum extinction at $530\text{--}540 \text{ m}\mu$.

How can this result be related to the present finding that extraction of the visual cells of the squirrel retina with digitonin solution yields a typical 'broad-band rhodopsin' with maximum extinction at about $500 \text{ m}\mu$?

There are no grounds for supposing that the discrepancy could be due to a gross difference between the light-absorbing properties of the pigment in the *in vivo* and extracted conditions. I have shown that the rhodopsin of the frog (visual pigment 502) has precisely the same absorption in the visual cell as it has after extraction into digitonin solution¹. This is true also of two other pigments which have been compared in this way, namely, the retinene₁ pigment of the conger eel (visual pigment 487) and the retinene₂ pigment of the carp (visual pigment 523) (Dartnall, unpublished work).

In any event, Weale (as he was aware) measured the difference spectrum of the squirrel pigment, not its direct absorption. Difference spectra (depending on the conditions under which they are obtained) may, or may not, be useful guides to the absorption spectra of the original visual pigments. In alkaline solution, for example, there is generally little overlap, in the visible, between the absorptions of visual pigments and their photoproducts. The positive portions of difference spectra consequently give good approximations to the original pigment absorptions. When the visual pigment is *in situ*, however, this is not the case. Thus a visual cell preparation of the frog pigment 502 can yield a difference spectrum maximal at $510\text{--}515 \text{ m}\mu$ (ref. 11). This is because a substantial amount of a stable $470\text{-m}\mu$ pigment is among the photoproducts formed under these conditions¹². Similarly, visual cell preparations of the conger pigment 487 and the carp pigment 523 likewise yield 'displaced' difference spectra, with maxima at 502 and $535 \text{ m}\mu$ respectively (Dartnall, unpublished work).

Reference has been made above to the presence, in bleached squirrel extracts, of a small amount of $480\text{-m}\mu$ pigment (in addition to the 'normal' retinene₁-protein). It is considered likely that in the water-free

Fig. 2. Comparison between the difference spectra (alkaline conditions) of the squirrel and hamster visual pigments. Squirrel data (20°C) from second extract; hamster data (25°C) from Bridges (ref. 7).

Fig. 3. Interpretation of *in vivo* measurements of the squirrel pigment and of the spectral sensitivity function. Circles (with bars indicating standard deviations) are Weale's results (ref. 10) for the density changes on bleaching the squirrel retina; crosses are Arden and Tansley's mean measurements of spectral sensitivity (equal quantum—intensity spectrum, corrected for lens absorption) (ref. 5). Both sets of results are scaled so that the maxima agree with that of the difference curve, that is, the difference between the 502 and 480 curves.

environment of the visual cell this substance may be formed in proportionately greater amount than in solution. If so, then a difference spectrum obtained *in vivo* would bear little resemblance to the spectrum of the original pigment.

In Fig. 3 an attempt has been made to formulate this idea in a semi-quantitative manner. The curves marked '502' and '480' represent the absorption spectra of the squirrel pigment and its 480-m μ photoproduct respectively. The curve marked 'difference' was obtained by subtracting the '480' curve from the '502' curve. It has a positive maximum at 533 m μ and a negative maximum at 448 m μ . Weale's results¹⁰ (shown by the circles in Fig. 3), when suitably scaled, agree tolerably well with this difference curve.

The shape (as distinct from the magnitude) of the difference curve is not markedly affected by the precise spectral location of the pigment and photoproduct curves. (Thus were we to assume a photoproduct at 470 m μ instead of at 480 m μ , the positive and negative maxima of the difference curve would be at 527 and 446 m μ respectively; for a 490-m μ photoproduct they would be at 537 and 452 m μ respectively.) Nor is its shape much affected by quite considerable variations in the relative heights of the pigment and photoproduct curves (arbitrarily shown equal in Fig. 3). We may conclude that the difference spectrum obtained by Weale in his *in vivo* experiments is consistent with that to be expected when a normal broad-band visual pigment having maximum extinction at about 500 m μ bleaches mainly or entirely to a substance having maximum extinction at about 480 m μ .

Amount of Pigment in the Squirrel Retina

At the wave-length of maximum change (c. 535 m μ), Weale observed a difference of density of 0.16 between

the unbleached and bleached retina. Assuming that the light by which this difference had been measured had passed twice through the pigment layer, he originally¹⁰ supposed the pigment density to be half this figure. One cannot be certain, however, that the measuring light does make such a double transit¹³. Consequently, it is safer to regard the values 0.08 and 0.16 as lower and upper limits respectively.

If the interpretation proposed in Fig. 3 for Weale's results is correct, it is clear that his maximum change amounts only to some 40 per cent of the density of the squirrel pigment. Allowance for this factor raises Weale's estimate from 0.08–0.16 to 0.20–0.40.

It is interesting to compare this value (a measure of the effective absorptivity of the pigment when in the retina) with that for the pigment when extracted. In the most efficient of the present experiments, nine squirrels were used, the isolated visual cells being twice extracted with digitonin solution (first and second extracts of Fig. 1). The residual retinae were likewise extracted twice. Adding the density results for all four extracts gives the total pigment yield as 0.55 ml. of extract of density 0.182 (per 0.5 cm.). Assuming the retina to be hemispheres of 1.15 cm. diameter, it is calculated that such a quantity of pigment would, if spread uniformly over the whole retinal area, cover it to an optical density of 0.0054.

The two values disagree grossly. Even after discounting a possible $3/2$ factor¹⁴ for increased absorptive efficiency due to orientation of the pigment molecules in the cones, the *in situ* estimate is still 25–50 times as great as that from extraction results.

Estimates of rod pigments *in situ* and after extraction normally agree fairly well when allowance for orientation and for the fraction of retinal area occupied by the rods¹⁴ is made. The present discrepancy with the squirrel cone pigment shows that the effective absorptivity of the pigment is greatly enhanced *in situ*, for example, by a mechanism which concentrates all the light incident on the inner segment of a cone into the smaller, pigment-containing area of the outer segment¹⁵.

Interpretation of the Squirrel Spectral Sensitivity Curve

Arden and Tansley⁵ have determined the spectral sensitivity of the grey squirrel from measurements of electroretinograms taken from animals under light nembutal anaesthesia. Their mean values (from two dark- and two light-adapted squirrels) are shown by the crosses in Fig. 3, and are seen to be in tolerable agreement with the difference curve.

This agreement suggests that the spectral sensitivity function may be mediated by a mechanism depending on the difference between the light absorbed by visual pigment chromophores and that absorbed by '480-' chromophores. The precise way in which this could occur is a matter for conjecture at present. One possibility, which has the merit of suggesting crucial electroretinogram experiments, is outlined below.

Hubbard and Kropf¹⁶ have suggested that when rhodopsin (in a dry film or at low temperature) is irradiated, "steady state mixtures of chromoproteins including photoregenerated rhodopsin and iso-rhodopsin" are formed. We shall postulate that in the water-free environment of the cone a similar situation arises, and that continuous irradiation results in a steady-state mixture of the 480-m μ pigment and photoregenerated squirrel rhodopsin. In other words, we postulate that the 480-m μ pigment formed when

squirrel rhodopsin bleaches is similarly photo-sensitive in the cone, and reverts totally or partially to the original pigment on absorption of light quanta.

Consider a cone which (as a consequence of its past history of exposure to light) contains approximately equal densities of 480- and 502-m μ pigments. If, now, this cone is exposed to light of wave-length about 490 m μ (which both pigments absorb equally, see Fig. 3) then the net changes in the pigment composition of the cone will be nil, for, on average, just as many 502-chromophores will be lost through bleaching as will be gained by photo-regeneration. Exposure of such a cone to any wave-length longer than 490 m μ will result in a net increase in 480-chromophores. Conversely, exposure to any wave-length shorter than 490 m μ will cause a net increase in 502-chromophores.

If we suppose that it is the change in chromophore constitution of the cone which ultimately provides the stimulus, then the sensitivity would be given by the modulus of the difference curve in Fig. 3. This modulus is a double-humped curve with maxima at 448 and 533 m μ and with a deep depression between, touching zero at about 490 m μ . Unfortunately, Arden and Tansley's observations were not extended far enough into the short wave-lengths to ascertain whether there is a second maximum of activity at about 450 m μ .

It has already been noted that the shape of the difference curve is not markedly affected by quite large variations in the relative heights of the 502- and 480-curves. Thus the form of the spectral sensitivity

curve for the mechanism proposed here would not change greatly over a wide range of cone compositions. One would expect, however, that a true threshold sensitivity function would reproduce the 502-curve alone. Conversely, if the cones contained virtually only the 480-m μ pigment (for example, after prolonged pre-adaptation to light of long wave-length) one would expect the spectral sensitivity to follow the form of the broad-band 480-curve.

I gratefully record my thanks to Mrs. M. R. Bright for assistance with the experiments and to Miss C. Kerr for tending the squirrels.

HOST SPECIFICITY OF TWO XANTHOMONAS SPECIES

By C. LOGAN

Cotton Research Station, Namulonge, Uganda*

DYE¹ has stated that he was able to adapt cultures of twenty species of *Xanthomonas*, after four successive passages through the leaves of young dwarf bean plants, to produce infection symptoms on bean leaves that could not invariably be distinguished from those caused by *X. phaseoli* (Smith) Dowson. This finding suggests that the host specificity of the xanthomonads may not be a stable character.

An attempt was made to adapt *X. malvacearum* to produce infection symptoms on the leaves of *P. vulgaris* var. Banja, similar to those produced by *X. phaseoli* var. *fuscans* (*X. phaseoli* and *X. phaseoli* var. *fuscans* cause similar disease symptoms on *P. vulgaris* leaves). In the first experiment the plants were grown in the greenhouse until the first trifoliate leaf was half-developed. They were then placed in a humidity chamber maintained above 70 per cent relative humidity and between 22° and 30° C. for 24 hr. and afterwards inoculated by needle with pure bacterial slime taken from 48-hr. old cultures grown at 27° C. on potato-sucrose-agar plus chalk. The plants were covered for 24 hr. with a transparent polythene bag. No difficulty was experienced in re-isolating *X. malvacearum* from the vein tissue immediately adjacent to the points of needle puncture, 7-9 days after inoculation. Six single colonies were mixed to provide inoculum for re-inoculation. The process of inoculation, isolation and re-inoculation was repeated six

times. On the 6th inoculation, leaves were also spray-inoculated by an atomizer with an aqueous suspension of the 'trained' bacterium from the 5th re-isolation until the leaves became water-soaked. As a control the leaves of another set of bean plants were sprayed with the original culture at approximately equal concentration (5×10^7 bacteria per ml.). The symptoms produced by the two cultures were similar, indicating that the successive transfers into bean tissue had not resulted in any alteration in its pathogenicity. Both bacterial cultures appeared to be capable of multiplying in bean tissue as the tissue of the sprayed leaves became slightly water-soaked in appearance 48 hr. after inoculation. After that time the tissue dried rapidly, forming light-brown necrotic areas. Both bacterial cultures caused, to the same degree, typical disease symptoms (angular leaf spot) when sprayed on to cotton leaves.

If the acquisition of new virulent characteristics is possible this must be engendered by some property or reaction of the new host plant and thus isolation and multiplication of the bacterium in pure culture is an unnecessary complication. In the second experiment bean leaves were used as the sole medium for multiplication of *X. malvacearum*. The technique was as follows: An aqueous suspension of *X. malvacearum* was prepared (approximately 5×10^7 bacteria per ml.) and sprayed by an atomizer on to the first and second trifoliate leaves (the second trifoliate was one-third fully developed) of 10 bean plants grown in the green-

* Present address: Plant Pathology Division, Ministry of Agriculture, Belfast, N. Ireland.

house. One half of each leaflet was sprayed until the tissue became water-soaked. Two to three days after inoculation disease symptoms became apparent as diffuse water-soaked areas. These did not increase in size and dried to form sunken, light-brown, necrotic areas (Fig. 1). One week after inoculation the necrotic areas from about 60 leaflets were cut out from the surrounding unaffected tissue and macerated in 150 ml. of distilled water. After standing for 3 hr. to allow the bacteria to diffuse out of the tissue, the suspension was filtered through muslin. The filtrate was used to spray the first and second trifoliate leaves of a second batch of bean plants. Some of the bacteria were lost by run-off during spraying, but a high proportion of the bacteria that had multiplied in bean tissue were re-inoculated into fresh tissue. The process was repeated seven times. The 'trained' bacterium was isolated, on solid media, from several necrotic areas which resulted from the seventh spray. Several single colonies were mixed together in distilled water to form a suspension (concentration of about 5×10^7 bacteria per ml.). An aqueous suspension of the original culture of approximately equal concentration was also prepared. The two were sprayed on to leaves of bean and on to leaves of resistant and susceptible varieties of cotton. Although the infection symptoms produced differed according to the host plant, the reactions of any particular host to the suspensions of 'trained' and 'untrained' bacteria were identical.

In an attempt to adapt *X. malvacearum* to break-down the resistance of the cotton variety BAR 12/15 (carrying the bacterial blight resistance genes B_2 and B_{6m}), the same 'training' procedure was employed as that described for the second experiment. The process of inoculation and re-inoculation of an aqueous suspension of the bacterium into BAR 12/15 leaf tissue was repeated 15 times. During the 'training' period there was no suggestion of any change in the pathogenicity of the bacterium to BAR 12/15 leaf tissue. This was confirmed by spraying both 'trained' and 'untrained' bacteria in aqueous suspension of approximately equal concentrations on to the leaves of two resistant and two susceptible varieties of cotton, when again no differences were apparent.

It was also found that there was no change in the virulence of *X. phaseoli* var. *fuscans* in response to a 'training' period in cotton leaf tissue involving 4 re-inoculations carried out as described in the second experiment. The 'trained' bacterium also retained its pathogenicity to *P. vulgaris*.

Fig. 1. The reaction of the bean leaf to either 'trained' or 'untrained' *Xanthomonas malvacearum* showing ill-defined, diffuse necrotic areas. ($\times 2$, lower surface)

Fig. 2. The reaction of the bean leaf to *Xanthomonas phaseoli* var. *fuscans* showing well-defined, typical lesions. ($\times 2$, lower surface)

In these experiments both *X. malvacearum* and *X. phaseoli* var. *fuscans* multiplied in the tissue of either cotton or bean leaves. When both species were sprayed on to bean leaves at a concentration of 5×10^7 bacteria per ml. similar symptoms were apparent after 48 hr. Both species induced the tissues to become slightly water-soaked in appearance, *X. malvacearum* to a lesser degree than *X. phaseoli* var. *fuscans*. After this time the symptoms became markedly different. The areas of leaves sprayed with *X. malvacearum* dried rapidly, forming light-brown necrotic areas (Fig. 1), while those sprayed with *X. phaseoli* var. *fuscans* became progressively more water-soaked, resulting in typical angular leaf spots (Fig. 2). When the concentration in inoculum was reduced to 5×10^3 bacteria per ml., *X. malvacearum*, 'trained' and 'untrained', caused no symptoms to develop on bean leaves whereas *X. phaseoli* var. *fuscans* caused typical infection.

Thus, in these experiments there was no change in the host specificity of two cultures of *X. malvacearum* or in the one of *X. phaseoli* var. *fuscans*, a marked contrast to the evidence presented by Dye, in whose paper three important points are omitted. (1) He did not mention whether the change in virulence was sudden or whether there was a gradual increase in severity of infection symptoms. He only stated that on the fourth inoculation, lesions were allowed to develop for seven days and that a progressive disease was produced by all twenty species of *Xanthomonas*. (2) He did not compare his 'adapted' bacterium with the original culture. (3) He did not reverse the experiment, that is, attempt to adapt *X. phaseoli* to any one of the twenty species of host plant. It is thus difficult to see how he can claim that a change did in fact occur in any of the twenty *Xanthomonas* species.

Because a close physiological and biochemical relationship exists between many of the 'phytopathogenic species' of *Xanthomonas*², it is generally considered that many of these, which have been named after the original hosts, should be regarded as having the status of formae speciales³, the differentiation of which is host specificity. If a further classification of the genus *Xanthomonas* is to be based on host reaction, the environmental conditions under which the host plants are grown, together with such considerations as the maturity of the host plant at time of inoculation, the inoculation technique or techniques, and the concentration of inoculum, must all be standardized.

LETTERS TO THE EDITORS

PHYSICS

Resonant Scattering of the 14-keV. Iron-57 γ -Ray, and its Interference with Rayleigh Scattering

WHEN radiation is scattered by a resonator, the question of its identity of frequency and coherence of phase with the incident radiation is not simply answered except for an infinitely narrow incident line, when the scattering is fully coherent (see, for example, the discussion by Heitler¹, written in the context of atomic resonances but equally relevant to nuclear ones).

Coherence may be experimentally proved by observing interference between the resonance radiation and some other form of scattering that is known to be coherent; for γ -rays, one would naturally look for interference with the Rayleigh (elastic electronic) scattering. In the long-studied 411 keV. resonance of mercury-198, such interference is unobservable², because of the thermal broadening of the line as well as for other reasons. It might just be observable in samarium-152, where the natural width of the 961-keV. line is not completely negligible^{3,4} in comparison with the thermal; but the best conditions appear to be provided by the very narrow low-energy lines discovered by Moesbauer⁵ in which a substantial part of the radiation is unaffected by recoil or thermal broadening.

After preliminary experiments in collaboration with Dr. B. S. Sood, in which the resonant scattering in metallic iron of the 14-keV. line of iron-57 was found to have the expected intensity, we decided that a foil of 65 per cent iron-57, electroplated on thin copper by the Isotope Division, Atomic Energy Research Establishment, Harwell, would give comparable amplitudes of resonant and Rayleigh scattering at convenient angles. We in fact chose an angle of $43 \pm 2^\circ$, which would include the (211) Bragg reflexion. The geometry of the apparatus is indicated in Fig. 1: the source⁶, about 20 mc. of cobalt-57 in a matrix of iron-56, was mounted on a 30 c.p.s. vibrator so that the exact energy of the emitted radiation could be oscillated through the resonant energy.

Fig. 1. Diagram of experimental arrangement. B, vibrator; S, source; C, proportional counter; F, iron foil. The shaded blocks are heavy alloy shielding. The different positions of the source and vibrator are: I, for scattering; II, for transmission; III and IV, for checking absence of shift in transmission.

Fig. 2. Plots of intensity versus velocity for transmission (dots) and scattering (circles). The zero of the velocity scale is fixed only by the position of the transmission minima. Positive velocities are for the source approaching the foil. The position M on the velocity scale is the point at which the acceleration reverses.

Auxiliary apparatus enabled the intensity of transmission through, or scattering from, the foil to be plotted automatically as a function of speed, the abscissae of the resultant graphs extending over rather more than half a cycle of vibration, so that passages through zero velocity in both senses of acceleration were displayed.

Fig. 2 shows the transmission minima and scattering maxima obtained; it will be seen that the scattering peaks are somewhat broader and slightly nearer to one another than are the absorption minima.

The reduced separation of the peaks was, however, due entirely to the shift of one of them; presumably the whole pattern had suffered an instrumental drift during the long periods of operation that were necessary. We repeated the measurements with the apparatus set to display negative, instead of positive, speeds at the centre, alternating transmission and scattering measurements and adding the results of all sets of each kind. Fig. 3 shows that the peaks now appeared, as expected, more widely spaced than the dips, with no evidence of general drift. Thus, assuming the transmission dips to occur at exactly zero velocity, we can say that the maximum scattering occurs when the source is approaching the scatterer with a velocity corresponding to a fraction of the line-width.

It remains to verify that the dips correspond precisely to zero velocity; this need not be so if source and scatterer materials are not identical. This point was checked at the suggestion of Mr. D. A. O'Connor, by successive transmission experiments with the source assembly set in the positions marked III and IV in Fig. 1; this amounts to reversing the velocity-scale about the true zero. No change in the dip position was found.

If there is some coherence of phase between resonant and Rayleigh scattering, we should expect them to be in quadrature at exact resonance, moving towards coincidence of phase on the high-frequency side. Thus, on top of the constant intensity of the Rayleigh and the sharply peaked contour of the

Fig. 3. Plots of intensity versus velocity for a separate experiment in which, as indicated on the velocity scale, negative velocities are displayed in the centre

resonant scattering, there should be added a dispersion-type curve representing the interference between them, with its maximum a fraction of a line-width to the positive side of zero velocity. The observed shift and broadening are probably to be explained in terms of such coherence, but the measurements are not yet detailed enough to show clearly the asymmetry of line-shape that is also to be expected or to determine what percentage of coherence exists; full coherence is not to be expected when the incident line is of similar breadth to that of the resonance.

We have also observed the resonant scattering from ordinary iron (2.2 per cent iron-57) at a mean angle of 90° , in the presence of a relatively large intensity of Rayleigh scattering. We found neither shift nor broadening of the scattering resonance, which is consistent with the expectation that, at this angle of scattering in a magnetic dipole transition, the resonant component will be polarized at right angles to the Rayleigh.

It is to be expected that the narrow-line resonance radiation will show, in its scattering from crystals containing iron-57, interference phenomena similar to those of X-rays. Interesting differences may arise from the resonant absorption which accompanies the scattering, from the narrowness of the line as compared with X-ray lines, and from the simple way in which the exact energy, and with it the phase of the resonant scattering, may be varied.

Specific Fall-out Activity in Precipitation as a Function of Sampling Height

IN 1956-57 Herbst *et al.*¹ found a definite increase with height in the fall-out activity in vegetation from an altitude of 800-1,000 m. and upwards. This was ascribed partly to the slow growth of the

vegetation with increasing height and consequently greater accumulation of activity on it, and partly to greater fall-out at increased heights. Small² suggested in 1958 from examination of the variations in the natural activity of the air (radium B and C), compared with the meteorological conditions at ground-level, that during inversion conditions the vertical transport of bomb debris from above would decrease. By comparing the fall-out in a precipitation collector situated in the top of a 123-m. mast with that in corresponding collectors at ground-level, I found³ for the period September 1958-March 1959 more fall-out in the former than in the latter.

It was therefore decided to examine the fall-out activity in precipitation collected in different heights. At Riso, a 123-m. meteorological mast has been built for micrometeorological measurements⁴. At heights of 0, 7, 23, 39, 56, 72, 96 and 123 m. I fixed, at a distance of 1 m. out from the mast, eight 1-litre polyethylene bottles each provided with a 154 cm.² polyethylene funnel. The bottles were changed on the first of every month.

After the bottles had been collected, the amount of rain-water in each was measured and strontium-, caesium- and cerium-carrier was added. The content of each bottle was then analysed for strontium-90 and -89, caesium-137 and cerium-144 by the method of Ormond *et al.*⁵. The activities are given in pc./m.³, and in pc./l., and are traced to the middle of the month. All the isotopes were determined for each of the ten months March-December 1959, except strontium-89 which was too weak in activity in the last months of the year for a reliable determination. A table with all the results of the measurements is given in Riso Report No. 14 (ref. 6). Table 1 gives the annual average values for the specific activity at the different heights.

A regression analysis on the figures in Table 1 shows for all the isotopes an increase in specific activity with the height. Strontium-90 displays an increase in activity of 15 per cent per 100 m., caesium-137 of 19 per cent, cerium-144 of 27 per cent and strontium-89 of 31 per cent.

A regression analysis of the results for the ratio strontium-89/strontium-90 (see Table 2) shows an increase in that ratio with height of 13 per cent per 100 m.

The present work shows that it is possible to detect a change in the specific activity in precipitation even within a difference in height of 100 m. (The increase in total fall-out with the height is still more significant, due to increasing amount of precipitation, when ascending⁶.)

The reason for this difference in specific activity must be due to the varying contribution of dry fall-out in the different rain-collectors, as it would be

Table 1. AVERAGE SPECIFIC ACTIVITY IN PRECIPITATION FOR THE PERIOD MARCH-DECEMBER 1959

Height (m)	Isotope			
	Strontium-90 (pc./l.)	Strontium-89 (pc./l.)	Caesium-137 (pc./l.)	Cerium-144 (pc./l.)

56	7.0
72	7.4
96	8.2
123	8.3

difficult to imagine how the rain could be less radioactive when falling down through the air.

(Regression analysis has shown that all the results are significant at the 1-2 per cent level except caesium-137 and the ratio strontium-89/strontium-90, which are significant only at the 10 per cent level.)

At an altitude of 60 m. above the Riso area, there are on the average inversion conditions during 25 per cent of the time⁴. In the lower regions inversion is more frequent, in the upper less. In accordance with Small's results⁵, it would be reasonable to suppose that these inversion conditions are one of the reasons why more dry fall-out is found in the bottles placed at the upper part of the mast than in those at the lower. Another factor contributing to the difference in activity will be the increasing wind velocity with increasing height⁴; this will give rise to a greater deposit of airborne particles in the higher bottles than in the lower ones⁷. Hence we get a higher specific activity in rain when the sample is taken at an altitude of, say, 100 m. than at ground-level.

Furthermore, it seems probable that short-lived fission products from fall-out would show a more pronounced variation with height than long-lived products. This is to be expected if one assumes that the dry deposit is of greater particle-size than the deposit from rain. Larger and heavier particles would be deposited more readily than fine particles⁷, and consequently the fine particles will consist preferentially of older fission products than coarse ones. As a consequence of this, the age of the fall-out will decrease with increasing sampling height of the precipitation. As an example, the age determined in March 1959 from the strontium-89/strontium-90 ratio was 170 days at 0 m. and 148 days at 123 m. above ground-level.

I thank Mr. Heinz Hansen and Mr. Ulf Christiansen for many stimulating and inspiring discussions, especially concerning the statistical evaluation of the results.

Radiative Transfer of Energy in the Core of a Heated Tube

WHILE investigating the temperature distribution along a thin-walled tube heated by passing an electric current through it *in vacuo* we had naturally to calculate the radiative transfer of energy occurring in the hollow core of the tube¹. Taking the tube to be a circular cylinder of diameter D , and considering an annular ring of width dx , the net gain in energy by the ring due to radiative transfer can be readily calculated. If the ring is not too near the ends, this is found to be equal to:

$$4\pi\sigma D^2 T^4 (dT/dx)^2 dx + \frac{4}{3}\pi\sigma D^2 T^3 (d^2T/dx^2)dx$$

which may be expressed in the form:

$$\frac{d}{dx} \left(\frac{4}{3}\pi\sigma D^2 T^3 \frac{dT}{dx} \right) dx$$

where σ is Stefan's constant of radiation, and the emissivity of the walls is taken to be unity. It is as though the hollow core had a thermal conductivity of magnitude:

$$\kappa_r = \frac{16}{3}\sigma DT^3 \quad (1)$$

One may compare this with the expression obtained by Bosworth² for the radiational conductivity of a very hot gas, in which the photons emitted by the molecules, as distinguished from the molecules themselves, are regarded as diffusing into the gas, his expression being:

$$\kappa_{rg} = \frac{16}{3}\sigma l_0 T^3 \quad (2)$$

where l_0 is the mean free path of the photons, which may be taken to be the reciprocal of the absorption coefficient of the gas for the photons. Indeed, the radiational conductivity of the hollow core may be regarded as the limiting case of the conductivity of a hot gas filling the core, when the pressure of the gas is reduced to zero and the free path of the photons is thus limited by the dimensions of the tube. In this limiting case the source of the photons will recede to the walls. Taking (2) to remain valid in this limiting case also, and comparing (1) with it, one can see that the mean free path of the photons in the hollow core is just D .

There is a close analogy between expression (2) for the radiational conductivity of a gas at high temperatures, and that for the lattice conductivity of a dielectric crystal at low temperatures, in which the transport of energy is by the low-frequency thermal elastic waves or phonons in the medium³. The closeness of the analogy arises ultimately from two factors: the upper limit to the wave number set by the Brillouin zone ceases to be of significance for these low-frequency waves, and, secondly, the frequencies are proportional to the wave numbers, as for the photons in a gas. These are also just the factors that lead to the T^3 law for the lattice specific heat.

The expression obtained by Casimir⁴ for the lattice conductivity of a dielectric cylinder at temperatures low enough for the free path of the phonons to be limited by its diameter is analogous to that obtained here for the radiational conductivity of the hollow core—again as though the mean free path so limited is just D .

When the emissivity of the walls falls short of unity, one has to know how the fraction $(1 - \epsilon)$ of the incident radiation that is not absorbed is returned to the enclosure. When it is in the form of specular reflexion, it is found that the thermal conductivity of the core is on this account increased by a factor $(2 - \epsilon)/\epsilon$, which is similar to the factor obtained by Berman, Simon and Ziman⁴ in their expression for the lattice thermal conductivity of a cylindrical specimen at low temperatures, and also similar to the 'coefficient of slip' of a rarefied gas in its passage through a narrow tube⁵.

Infra-Red Spectrum of Praseodymium Nitrite

In researches undertaken in this Laboratory, it has been necessary to characterize certain species in the thermal decomposition of a number of metal nitrates. In order to do this, it has been found useful to obtain the spectra of a number of metal nitrites. Nitrites are known to occur in the course of decomposition of a number of metal nitrates¹; it has been found that praseodymium nitrite is a transient product in the thermal decomposition of praseodymium nitrate². Praseodymium nitrite also appears as an intermediate in the interaction of nitrogen dioxide on praseodymium (Honig, J. M., and Vratny, F., unpublished work).

The majority of the nitrites used for comparison were obtained from commercial sources. Praseodymium nitrite was prepared by the method of Dutta³ and Ferrari, Cavalea and Nordelli⁴. Stoichiometric quantities of praseodymium chloride and silver nitrite in aqueous solution were combined. The product was obtained by vacuum evaporation of the water. The viscosity of the ensuing solution, difficulty in crystallization, etc., strongly resemble the nitrate in character⁵.

The spectra of the powdered metal nitrites were obtained on a double-beam Perkin Elmer model 21 spectrometer using sodium chloride optics. The spectra were obtained by dispersing the solid in 'Nujol' and by forming a potassium chloride pellet. The spectra were essentially the same except in the case of barium nitrite, in which case there appeared to be a shift in the 1,282-cm.⁻¹ band to 1,240 cm.⁻¹ in 'Nujol'. The use of the dual technique is recommended to assure absence of exchange, etc.⁶.

The spectra of the simple nitrites: sodium, potassium, silver and barium, are rather straightforward and follow the characterization formulated by Williams⁷. The band at about 830 cm.⁻¹ represents the ν_2 bending mode, the band at about 1,250 cm.⁻¹ is the ν_1 symmetric stretching, and the band at about 1,360 cm.⁻¹ is the ν_3 asymmetric stretching. The

Fig. 1. Correlation diagram for various metal nitrites

splitting observed in the case of $\text{Co}(\text{NH}_3)_3(\text{NO}_2)_3$, occurs most probably in the ν_2 vibration and is configurational in origin. The spectrum of praseodymium nitrite is still more complex in that even greater splitting has occurred. The magnitude of the splitting is correspondingly greater than the field splitting observed in metal nitrates⁸. The distinction between nitro- and nitrite-linkage, as occurs with silver and sodium nitrite⁹, is not a determining factor in this case. Recent work reported by Gatehouse¹⁰ has shown that changes can be expected in the spectra of metal nitrites when the nitrite groups are arranged in either a *cis* or *trans* arrangement as in the case of $\text{Co}(\text{NH}_3)_3(\text{NO})_3$, or when the nitrite group gives rise to a bridging structure, namely:

The spectra for two such compounds, reported by Gatehouse, are given in Fig. 1 along with other observed spectra. The two important modes of vibration for the bridging structure are:

at about 6.8 and 8.3 μ , respectively. It can be seen that four characteristic bands occur in the high-energy region of the spectrum.

Fig. 2. Infra-red spectrum of praseodymium nitrite in 'Nujol' and potassium chloride pellet

The splitting produced in praseodymium nitrite strongly suggests a similar bridging structure. For purposes of comparing band intensities, the spectrum of praseodymium nitrite is reproduced in Fig. 2.

CHEMISTRY

Invariance of Molecular 'Inverse' Force-constants

In the quadratic form:

$$V = \frac{1}{2} \sum_i \sum_j k_{rs} q_i q_j \quad (k_{rs} = k_{sr}) \quad (1)$$

representing the harmonic approximation to the potential energy of a vibrating molecule, the 'force constants' k_{rs} depend on the definition of the internal co-ordinates q_i used to represent small changes in the molecular configuration. For example, a full analysis¹ of the vibrations of ¹⁴NO, and ¹⁵NO, with co-ordinates q_1 and q_2 the NO bond stretches, gives for the stretch and stretch-interaction constants $k_{11} \equiv k_{11}$, and k_{12} , the following values (in units 10⁵ dynes/cm.): (i) 10.884 and 1.9914 and (ii) 15.507 and 6.614 in the two cases where the third co-ordinate is (i) the ONO angle distortion and (ii) the change in OO distance. Thus the interpretation and comparison of force-constants obtained by different co-ordinate analyses present difficulties, which naturally increase with molecular complexity.

'Inverse' force-constants, h_{rs} , may be defined as the elements of the matrix $\{h_{rs}\}$ inverse to $\{k_{rs}\}$. A changed definition or choice of the internal co-ordinates q_i corresponds to a linear transformation, and the necessary invariance of V in (1) under this transformation implies that the h_{rs} can be transformed like the dyad or set of products $q_i q_j$. Thus if new co-ordinates $q_1, \dots, q_n$ (linear combinations of the old $q_1, \dots, q_n$) are chosen, leaving the old q_1 and q_2 as members of the new set, then the elements h_{11} , h_{12} and h_{22} are unchanged; and in general, the inverse force-constants corresponding to any unchanged co-ordinates are invariant. This can be verified with precision by using full sets of force-constants k_{rs} for NO, in cases (i) and (ii) above.

This invariance of inverse force-constants holds similarly for the potential energy in the vibrations of a single symmetry class, where the k_{rs} are sym-

metry-co-ordinate force-constants, and a partial change is made in the choice of symmetry co-ordinates.

It has often been found useful tentatively to transfer one or more force-constants k_{rs} from one fully analysed molecule to another containing a similar atomic group. The present considerations suggest that it might be more suitable to transfer the corresponding *inverse* force-constants h_{rs} .

Re-assessment of the Electron-spin Resonance Splitting Constants of Several Well-known Free Radicals

THE hyperfine splitting constants of the electron-spin resonance spectra of several well-known free radicals in solution have been re-measured recently. In some cases discrepancies with the values quoted in the literature have been found.

The particular case examined was the detection and identification by electron-spin resonance of a free radical produced during the thermal cracking of hydrocarbons, as the perinaphthenyl radical (it is hoped to publish details of this work in due course). It was found that the values of the splitting constants for the perinaphthenyl radical differed from those already reported¹. In order to check the calibration of the magnetic field, the splitting constants of several well-known free radicals were measured, and the values obtained in the present work are compared with those reported in the literature in Table 1. The accuracy of the magnetic field calibration is confirmed by the agreement obtained for the last two free radicals listed. (Similar agreement has been obtained for several other free radicals.)

Table 1. HYPERFINE SPLITTING CONSTANTS FOR FREE RADICALS IN SOLUTION

* α,α'-Diphenyl-β-picrylhydrazyl.

† 1,3-Dimethyl-1-(phenylaluminoxide)-butylidene-3-N'-phenyl-N'-oxymyrogen.

‡ 2,6-Di-*t*-butyl-4-(3,5-di-*t*-butyl-4-oxocyclohexa-2,5-dienylidene methyl)phenoxy.

In view of the potential use of electron-spin resonance for identifying unknown free radicals, the need for an accurate measurement of the hyperfine splitting constants cannot be emphasized too strongly. The apparatus used for measuring the magnetic field was relatively simple, consisting of a proton resonance probe and a BO 221 crystal-controlled frequency meter. In most cases the derivative electron-spin

resonance spectra were obtained and field markers superimposed on the recorder trace. In a few instances the spectra and the proton resonance signal were displayed on an oscilloscope and the hyperfine splittings measured directly.

Hydrogen-bonding in Calcium-deficient Hydroxyapatites

MANY calcium phosphates precipitated from solution give the X-ray diffraction pattern of hydroxyapatite but depart from the ideal stoichiometry, $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$, of this compound. Pure hydroxyapatite can be prepared only under hydrothermal bomb conditions^{1,2}, whereas the appearance of hydroxyapatites with low Ca/P ratio from aqueous preparations seems to be the rule rather than the exception.

Index of refraction, density, and X-ray diffraction data have shown that it is possible to have calcium ions missing randomly from certain positions in the hydroxyapatite structure³. To effect electrical neutrality, it was suggested that hydrogen bonds, in the proper proportion, were present between the oxygens of adjacent orthophosphate groups³. Evidence is presented here to confirm the presence of hydrogen bonds in a series of hydroxyapatites, with low calcium, in proportion to the missing number of calcium ions.

A series of hydroxyapatites deficient in calcium were prepared by methods outlined in an earlier publication⁴, and examined by X-ray diffraction to make certain that each preparation was a single phase. The samples were analysed for calcium gravimetrically⁵, and for phosphorus by a differential spectrophotometric method⁶. Average indices of refraction of the samples, obtained by the double-diaphragm method of oblique illumination⁷, confirmed the X-ray and chemical evidence that these samples were calcium-deficient hydroxyapatites. Details of all physical and chemical analyses will be given in a later publication.

The samples all show an infra-red absorption band near 3,400 cm^{-1} , which corresponds to a hydrogen-bonded O—H stretching frequency. Weighed mixtures of the various calcium-deficient hydroxyapatites and potassium ferriocyanide were prepared and examined in a commercial infra-red spectrophotometer. Spectra were obtained from a pressed film of the sample held between two sapphire windows of

Fig. 1. Right. Plot of relative molar absorbance, A , at 3,400 cm^{-1} against the Ca/P molar ratio of a series of calcium-deficient hydroxyapatites.

Left. Plot of absorbance values (A) against the number of gram atoms of H per mole (x) of calcium-deficient hydroxyapatite as calculated by theory (ref. 3). Standard deviations in ordinate and abscissa are indicated at each point. A was calculated by dividing the absorbance per mole at 3,400 cm^{-1} by the absorbance per mole of internal standard (potassium ferriocyanide) at 2,105 cm^{-1} .

a sapphire pressure-cell⁸. The base-line technique was used to calculate the molar absorbance from the absorption band. The hydrogen-bond content was determined quantitatively by comparing the absorbance at 3,400 cm^{-1} with that of potassium ferriocyanide at 2,105 cm^{-1} . The latter was used as an internal standard to correct for the unavoidable differences in thickness of film of the samples.

Fig. 1 shows that in a series of low-calcium hydroxyapatites examined, the infra-red absorption due to the hydrogen-bonded O—H group is inversely proportional to the Ca/P ratio. If the general formula for hydroxyapatite is assumed³ to be $\text{Ca}_{10-x}\text{H}_x(\text{PO}_4)_6(\text{OH})_2$, it is then possible to plot the relative molar absorbance, A , against $2x$ (the gram atoms of hydrogen). Fig. 1 shows that such a plot is a straight-line function, indicative of the validity of the formula assumed.

The value of A approaches zero as the Ca/P molar ratio approaches 1.67, that is, the ratio for pure hydroxyapatite. Thus when the hydrogen-bond content is zero (that is, when $x = 0$), the compound is the end member, hydroxyapatite, which contains no hydrogen-bonding but only exhibits the O—H stretching frequency of free hydroxyl ion near 3,700 cm^{-1} .

The hydrogen-bonded O—H stretching frequencies observed in the samples of calcium-deficient hydroxyapatites were all found to be near 3,400 cm^{-1} . This indicates that the oxygen-to-oxygen distance of the O—H—O bonds did not change with varying hydrogen content. By means of the criteria of Lippincott and Schroeder⁹, the probable O—O distance calculated from the O—H stretching frequency can be estimated at 2.85 Å. This is a reasonable distance between oxygen atoms of adjacent orthophosphate groups clustered around the three-fold axes of hydroxyapatite as calculated from the refined atomic parameters of this crystalline species¹⁰. It is not possible to say specifically from the present results which oxygen atoms are involved in the hydrogen-bonding. However, it is reasonable to assume that the hydrogen bonds will be as near as possible to the missing columnar calcium positions on the three-fold axes, since electrical neutrality will be maintained locally in a crystal.

This experiment has implications beyond the synthetic calcium phosphates discussed here. It has been suggested that the mineral portions of bone and tooth tissue are calcium-deficient hydroxyapatites^{3,11}. The possible presence of hydrogen bonds in these materials may provide a much needed parameter for an estimation of the stoichiometry of these biological hydroxyapatites under varying conditions. In addition, there are many non-stoichiometric, inorganic systems in which hydrogen-bonding between electro-negative ions may provide a balance between chemical perfection and imperfection due to missing cations.

The 1,2-Propylenediaminetetra-acetato-cobaltate(III) Anion

It is implicit in a recent theory¹ of stereospecific effects in metal complexes containing optically active diamines that the optical isomers of complexes containing only one such diamine molecule should have exactly similar conformations.

To test this matter, the infra-red spectrum in the sodium chloride region of L-potassium (*d*-propylenediaminetetra-acetato)-cobaltate(III) trihydrate was compared with that of DL-barium (*dl*-propylenediaminetetra-acetato)-cobaltate(III) octahydrate. The spectra, in 'Nujol' mulls, were identical, as predicted by theory¹. It is of interest that the infra-red spectra of *d*- and *dl*-propylenediamine tetra-acetic acids are not quite identical². This was attributed to differences in hydrogen bonding.

A further point of interest is that the spectra of the cobalt complexes show a single strong carboxylate peak at 1,647 cm⁻¹. This is good evidence for hexacoordination by propylenediaminetetra-acetate, and is directly analogous to the single strong peak in the infra-red spectrum of the (ethylenediaminetetra-acetato)-cobaltate(III) anion (ref. 3). The spectra of complexes with copper(II), zinc and nickel show a splitting of this peak, presumably due to pentacoordination.

The cobalt complexes used were prepared by the methods given by Dwyer and Garvan³. Attempts to make complexes of formula (Co(HPDTA)X)⁻, where PDTA is the propylenediaminetetra-acetate ion and X is the bromide or nitrite ion, by methods like those used by Schwarzenbach⁴ in making the corresponding complexes of ethylenediaminetetra-acetate were unsuccessful. However, the reaction mixture from the attempted introduction of nitrite ion had a visible absorption spectrum which differed from that of the (propylenediaminetetra-acetato)-cobaltate(III) anion.

I thank Dr. G. D. Meakins for providing infra-red facilities and Dr. H. M. Irving for his help.

BIOCHEMISTRY

Effect of Electrolytes on the Activity of Glutamic-Oxalacetic Transaminase

In their method for the determination of glutamic-oxalacetic transaminase without precipitation of protein, Mohun and Cook¹ conducted transamination between aspartic and α -ketoglutaric acid to glutamic and oxalacetic acid in a phosphate buffer solution of pH = 7.5. Similarly, Yatizidis² used a 2 per cent solution of dipotassium hydrogen phosphate for incubation of the system previous to determining the enzyme activity in the serum.

Transaminase activity is known to be enhanced by iron Fe²⁺ and magnesium ions^{3,4} and impeded by mercury and cyanide compounds⁵. Introduction of nickel, cobalt, aluminium and manganese ions was found to produce no variation in the activity of the enzyme⁶.

As defined by Cabaud⁷, the unit of transaminase activity is that of 1 ml. of serum giving rise to 1 μ gm. of pyruvic acid in the system incubated. The activity of the serum investigated is determined by the use of a standard graph obtained from extinction measurements in hydrazone solutions of various pyruvic acid concentrations.

In the present investigation, which was carried out according to the method proposed by Mohun, the composition of the fundamental solution containing the substrate, that is, aspartic and α -ketoglutaric acid, was made to vary. In addition to the buffer solution, some electrolyte solutions as well as pure distilled water were used as solvents, simultaneously with, or instead of, the buffer. The experimental

Table 1

No.	Medium	Electrolyte introduced, in mgm. per sample	pH of system	SGO-T in Cabaud units
1	Phosphate buffer according to Mohun	9.4	7.5	22
2	Buffer-water (1:3)	2.4	7.5	33
3	Distilled water	—	5.0	34
4	Sodium chloride	8.2	4.8	25
5	Sodium chloride + (buffer-water (1:3))	10.6	7.4	24
6	Potassium chloride	9.6	4.8	29
7	Calcium chloride	1.4	4.9	43
8	Magnesium chloride	2.0	4.9	49

results are shown in Table 1, and prove that the activity of the enzyme increases as mineralization of the system decreases and acidity rises, attaining 34 Cabaud units in a medium of distilled water. The presence of sodium chloride and potassium chloride does not induce such activity. On the contrary, addition of calcium chloride or magnesium chloride to the solution incubated raises serum transaminase activity above the level obtained in an aqueous solution without electrolyte admixture, in spite of the relatively small amounts of calcium chloride and magnesium chloride introduced (greater amounts of calcium chloride provoke precipitation of sediment with substrate).

Isocitratase as an Enzymic Indicator of Metabolic Pathways

MANY micro-organisms form major quantities of isocitratase only when grown on substrates the catabolism of which ultimately produces acetate, and the provision of even small quantities of intermediates of the tricarboxylic acid cycle represses this formation of the enzyme¹⁻³. This property can be utilized to decide between alternative modes of microbial degradation of growth substrates if one such alternative leads ultimately to the formation of acetate (or acetyl coenzyme A) and the other does not.

Table 1. ISOCITRATASE ACTIVITY IN CELL-FREE EXTRACTS OF *Pseudomonas ovalis* CHESTER GROWN ON VARIOUS CARBON SOURCES

Carbon source for growth	Specific activity of isocitratase
Lysine	4.8
Glutaric acid	5.1
Acetone dicarboxylic acid	4.8
Acetoacetic acid	5.0
Acetic acid	5.2
α -Hydroxyglutaric acid	0.04
α -Ketoglutaric acid	0.05
Glutamic acid	0.05

Pseudomonas ovalis Chester was grown at pH 7.2 in 50 ml. of medium (ref. 1) containing 50 mM ammonium chloride, 50 mM phosphate, essential salts and the carbon source at 50 mM concentration. Extracts were prepared from the washed cells as previously described (ref. 1) and assayed for isocitratase (ref. 12). The levels of the enzyme in the extracts are expressed as the specific activity (μ moles of glyoxylate formed from isocitrate/hr./mgm. protein)

An example of this is the catabolism of lysine. Studies with mammals and mammalian tissue preparations have established⁴⁻⁷ that lysine is catabolized via pipecolic and α -amino-adipic acids, to glutaric acid. The subsequent fate of glutaric acid is, however, in some doubt. Evidence has been obtained both for its β -oxidation to acetate^{5,7-9}, via acetone dicarboxylic acid and acetoacetate (path A), and its alternative α -oxidation^{4,10,11} to α -ketoglutarate or glutamate via α -hydroxyglutarate (path B); the relative quantitative contribution made by these routes is not clear.

In an attempt to assess the relative importance of these two pathways in *Pseudomonas ovalis* Chester, the organisms were grown on media containing respectively lysine, or the sodium salts of glutaric, acetone dicarboxylic, acetoacetic, acetic, α -hydroxyglutaric, β -ketoglutaric and glutamic acids as sole sources of carbon. The isocitratase activity of extracts of cells thus grown was measured¹² (Table 1). Growth on the first five carbon sources listed in Table 1 (lysine and the substrates of path A) was accompanied by high and uniform levels of isocitratase, which indicates that their catabolism led chiefly to acetate. Growth on the last three substrates (the substrates of path B) led to formation of only traces of the enzyme.

Although these results do not provide evidence that the first five carbon sources listed are necessarily interrelated and are intermediates in the microbial degradation of lysine, they nevertheless show that the pathways of their catabolism are similar in leading to acetate, and different from the modes of degradation of the last three carbon sources. Since the specific activity of isocitratase after growth on lysine is closely similar to that produced after growth on postulated intermediates of its oxidation via path A and on the ultimate product, acetate, these results are consistent with its catabolism via this or some similar route also leading to acetate, and rule out path B as of quantitative importance in this organism. These findings are also in agreement with those of Andreoli and Wolfe¹², that oxidation of glutaric acid by an organism isolated from soil involves β -oxidation rather than α -oxidation.

I am grateful to Sir Hans Krebs for his encouragement and interest, and to Miss Patricia Lund and Mr. C. J. Swale for their technical assistance. Estimation of Magnesium and Purification of Chlorophyll from *Chlorobium thiosulphatophilum*

Chlorobium thiosulphatophilum was grown under conditions similar to those described by Larsen¹. 'Chlorobium chlorophyll' (bacterioviridin) was extracted from the cells with 80 per cent methanol, transferred to ether, washed with water and dried over anhydrous sodium sulphate. The volume of the solution was reduced by evaporation under nitrogen, and the bulk of the chlorophyll precipitated by the addition of petroleum ether (b.p. 60-90). The chlorophyll was collected on talcum and washed with petroleum ether (b.p. 30-60) until the washings were colourless. The chlorophyll was removed from the talcum with acetone, transferred to ether, and washed with water. After drying, the solution was concentrated under vacuum, an equal volume of petroleum ether (b.p. 60-90) containing 4 per cent tetrahydrofuran added, and the solution adsorbed on to a sucrose column. The tetrahydrofuran was employed as a means of preventing precipitation of the chlorophyll

in the column². The column was developed by stepwise elution with isopropyl alcohol (0.75-2.0 per cent) in petroleum ether (b.p. 60-90) containing 2 per cent tetrahydrofuran. The chlorophyll zone was cut out, dissolved in ether, and chromatographed as before. The absorption spectrum of the chlorophyll in ether was obtained on a Cary recording spectrophotometer. Peaks at 650, 575, 530, 425, and 406 m μ indicated that this chlorophyll was the '650' type described by Stanier and Smith³, and that the organism studied was similar to or identical with *Chlorobium thiosulphatophilum*, strain L.

The magnesium content of the purified chlorophyll was determined spectrophotometrically by formation of a magnesium complex with sodium 1-azo-2-hydroxy-3-(2,4-dimethylcarboxanilido)-naphthalene-1'-(2-hydroxy-benzene-5-sulphonate)⁴. The purified chlorophyll, containing 0.5-1.0 μ gm. of magnesium, was evaporated in a platinum dish, ashed with sulphuric acid, and collected as described by Koski and Smith⁵. The procedure was modified by keeping the total volume of water to less than 5 ml., and using 95 per cent ethanol for rinsing. The pH of the ethanolic solution of magnesium was adjusted to be slightly acid to phenolphthalein and transferred to a 25 ml. volumetric flask. Five ml. of the naphthalene-sulphonate reagent (0.15 mgm./ml. in 95 per cent ethanol) and 0.5 ml. of 0.08 M borax solution were added, the solution brought to volume with 95 per cent ethanol, and mixed. After 1 hr. the absorbance of the solution at 510 m μ was measured in a Beckman DU spectrophotometer using a distilled water blank and the concentration of magnesium in the solution calculated from a standard curve. The spectrophotometric sensitivity of this method is 0.0008 μ gm. of magnesium/cm.² as compared with a sensitivity of 0.006 μ gm. for the titan yellow method.

Assuming that there is a 1:1 molar ratio of magnesium and chlorophyll, the calculated molar extinction coefficient at 650 m μ in ethyl ether is 99.7×10^3 . Using the value for the specific extinction coefficient at 650 m μ obtained by Stanier and Smith³ for 'Chlorobium-chlorophyll-650' (113.5 l./gm. cm.) the calculated molecular weight of the chlorophyll was 879.

This work was carried out under the auspices of the U.S. Atomic Energy Commission.

Tryptic and Phosphatase Action on Certain Synthetic Phosphorylated Peptides

With the development of a new procedure for the synthesis of O-phosphorylated peptides, in which di-*p*-nitrobenzyl phosphorochloridate is used as the phosphorylating agent¹, we have had occasion to study the action of alkaline and acid phosphatase on certain synthetic substrates.

A preliminary report of our results seems to be justified from the fact that a correlation between chemical structure and phosphatase action is strongly suggested. Moreover, additional information on the inhibitory spectrum of phosphoserine² was gained by the synthesis of α -carbethoxy-L-lysyl-L-leucyl-L-(O-phospho)serine and the action of trypsin on it.

So far as the latter case is concerned, the key intermediate, α -carbethoxy-(ϵ -carbobenzoxy)-L-lysyl-L-leucyl-L-serine benzyl ester (I), was prepared in a similar series of reactions used in the preparation of α -carbethoxy-(ϵ -carbobenzoxy)-L-lysyl-L-seryl-glycine benzyl ester³; the product had $[\alpha]_D^{25} - 19.6^\circ$ (c. 1 in glacial acetic acid). Analysis: calc., $C_{33}H_{46}N_4O_8$; C 61.6; H 7.1; N 8.7; found: C 61.6; H 7.1; N 8.6. Hydrogenolysis of it produced α -carbethoxy-L-lysyl-L-leucyl-L-serine (II) with $[\alpha]_D^{25} - 28.5^\circ$ as 1 per cent solution in glacial acetic acid.

Phosphorylation¹ of I and subsequent removal of protecting groups with palladized charcoal afforded α -carbethoxy-L-lysyl-L-leucyl-L-(O-phospho)serine (III), m.p. 245–250° (Kofler block), $[\alpha]_D^{25} - 24.5^\circ$ (c. 1 in glacial acetic acid). Analysis: calc., $C_{18}H_{28}N_4O_{10}P$; N 11.2; P 6.2; found: N 10.9; P 6.1.

Fig. 1. ●, α -Carbethoxy-L-lysyl-L-seryl-glycine; ○, α -carbethoxy-L-lysyl-L-leucyl-L-serine; x, α -carbethoxy-L-lysylglycyl-L-serine. Hydrolysis of substrates (0.01 M) with 1 per cent trypsin (three times crystallized, Fluka preparation), pH 8.2 (Tris buffer) at 25°C

The result of the tryptic action on substrate II is indicated in Fig. 1. Evidently, compound II is hydrolysed faster than α -carbethoxy-L-lysylglycyl-L-serine (obtained from hydrogenolysis of α -carbethoxy-(ϵ -carbobenzoxy)-L-lysylglycyl-L-serine benzyl ester¹) and slower than α -carbethoxy-L-lysyl-L-seryl-glycine. It must be emphasized, though, that the colour yield given by the splitting products has not been taken into account; but, so far, only leucyl peptides are reported to give very low colour yield with the ninhydrin reagent⁴.

Compounds II and III were incubated with trypsin at pH 8.2 at 25° and the incubation mixtures were then checked by paper chromatography at different intervals up to 2 hr. In contrast to II, compound III was extremely slowly attacked by trypsin. Only traces of the splitting product, L-leucyl-L-(O-phospho)serine, could be detected. Even after 18 hr. when II was completely hydrolysed, compound III gave a faint spot at the position of L-leucyl-L-(O-phospho)serine.

It might be of interest to note that the splitting of II by trypsin is not inhibited in the presence of III. Similarly, α -carbethoxy-L-lysyl-L-(O-phospho)-seryl-

Fig. 2. Dephosphorylation of substrates (0.01 M) with alkaline phosphatase (0.1 mgm./ml., crude preparation, Fluka) in barbiturate buffer (0.2 M) pH 9.4 at 38°C. L-Ser-P = L-phosphoserine; D,L-Ser-P = D,L-phosphoserine

glycine (m.p. 260–262°, Kofler block) does not retard the hydrolysis of α -carbethoxy-L-lysyl-L-seryl-glycine, when both substrates, in the ratio 1:1, 2:1 and 3:1, are incubated with trypsin. Since no competitive inhibition was observed under these experimental conditions, it seems reasonable to assume that the resistance of the above-mentioned phosphopeptides towards trypsin is due to the intense electrostatic field which results from the vicinity of a strongly acidic (phosphoric acid) and a basic group (ϵ -amino group of lysine).

It should be recalled that L-(O-phospho)seryl-L-glutamic acid, isolated by Posternak and Pollaczek, was resistant to the dipeptidase action, but sensitive

Fig. 3. Dephosphorylation of substrates (0.01 M) with acid phosphatase (0.1 mgm./ml., Lot 8055 Nutritional) in citrate buffer (0.1 M) pH 4.9 at 38°C.

to this enzyme after dephosphorylation⁵. Another tetrapeptide Ileu.SeP.Val.Arg. was only slowly attacked by leucine aminopeptidase, while the hexapeptide, Lys.Glu-NH₂.Ileu.SeP.Val.Arg., readily yielded a mixture of lysine, glutamine, glutamic acid and a large amount of the tetrapeptide possessing an amino-terminal isoleucyl residue⁶.

Provided that essential phosphopeptides are produced during the breakdown of caseins, one could assume that, in this connexion, the phosphoserine residues might play an important part in controlling the selective splitting of peptide bonds. Additional support to this assumption is offered by the phosphatase specificity observed with certain synthetic substrates tested so far.

It is apparent from Fig. 2 that alkaline phosphatase dephosphorylates glycyl-D,L-(O-phospho)serine (Gly.SeP) considerably faster than L-(O-phospho)-seryl-L-alanine (SeP.Ala), calculated as the monohydrate.

Acid phosphatase, on the other hand, was found to dephosphorylate L-(O-phospho)seryl-L-alanine faster than glycyl-D,L-(O-phospho)serine. The amount of phosphorus liberated was determined by the method of Fiske and Subbarow⁷.

Ubiquinone (Coenzyme Q) in Insects

Lester and Crane¹ found that while tissues of vertebrates contain mostly the Q₁₀-homologue of ubiquinone (coenzyme Q), certain insects, notably the house-fly, *Musca domestica*, and the cabbage white butterfly, *Pieris rapae*, are characterized by the presence of the Q₉ homologue, that is, a ubiquinone with a side-chain of 9, instead of 10, isoprenoid units.

In continuation of our previous work on quinone-dependent respiratory systems in insects^{2,3}, we made an analysis of ubiquinone in the hawk-moth, *Olerio euphorbiae*. The fresh tissue was saponified, extracted with ether, the extract washed with water, concentrated to dryness, and the residue dissolved in absolute ethanol. The absorption of ultra-violet light due to the ubiquinone present in the ethanolic solution showed a peak at 272 mμ; but we found it impossible to shift it to 291 mμ by reduction with potassium borohydride. In order to purify the material, the ethanolic solution was kept at -15° for 2 days, the precipitate which had appeared was removed, and the supernatant solution instilled on Whatman chromatographic paper No. 1, impregnated with 'Vaseline'. The chromatogram was developed in 95 per cent ethanol, and the paper area corresponding to the ubiquinone eluted with absolute ethanol. In this solution it was possible to demonstrate the character-

istic shift of the absorption maximum from 272 to 291 mμ, which occurs after reduction.

In order to identify the ubiquinone homologue obtained from the hawk-moth, the chromatographic method of Page *et al.*⁴ was used. However, instead of dimethylformamide, 95 per cent ethanol was employed for developing the chromatograms. In this way, it has been possible to achieve a much better separation of authentic samples of the Q₉ and Q₁₀ homologues, which had been prepared from the yeast *Torula utilis*, and ox heart, respectively, using a modified method of Crane *et al.*⁵.

In addition to the hawk-moth, *Olerio euphorbiae*, desiccated material from two other species of insects has been examined, namely, the pupae of *Sphinx pinastri* (Lepidoptera) and the adult insects of *Anatis ocellata* (Coleoptera). Just like the hawk-moth, the other two species have been found to contain the Q₁₀ homologue of ubiquinone.

A detailed account of the experiments will be published in *Acta Biochimica Polonica*.

The Epoxide Nature of the Carotenoid, Neoxanthin

In his extensive investigation of the xanthophylls of leaves, Strain¹ described a common, widely distributed carotenoid which he named neoxanthin. Neoxanthin has since been reported by other workers, and the evidence suggests that, together with lutein and violaxanthin, it is one of the three major xanthophylls of leaves^{1,2}. Despite its common occurrence, however, all that is known of this pigment is due to Strain.

Neoxanthin is characterized by: (1) its tight adsorption on chromatographic columns of magnesium oxide or aluminum oxide, where it is found above lutein, violaxanthin, and flavoxanthin; (2) its characteristic absorption spectrum, similar in shape and position to violaxanthin, and with more pronounced fine structure than lutein; (3) its solubility—neoxanthin is readily soluble in alcohol but only sparingly soluble in petroleum ether. On partition between 60 per cent aqueous methanol and petroleum ether, the pigment is found almost entirely in the hypophase¹.

Goodwin and Jamikorn³ reported the presence of neoxanthin in the green flagellate, *Euglena gracilis*. Recently we too have found a pigment in this species which has similar spectral and adsorptive properties to the neoxanthin described by Strain. Strain worked much with barley. We have therefore compared this carotenoid to neoxanthin isolated from barley (*Hordeum*).

Fig. 1. (A) Absorption spectrum in ethanol of neoxanthin isolated from *Euglena* (dashed curve) and barley (dotted curve) (B) Absorption spectrum in ethanol of the furanoid oxide produced from neoxanthin in the presence of traces of dilute hydrochloric acid

The tissues were dried by grinding with anhydrous sodium sulphate and the pigments extracted with acetone and ethanol. After saponification, the carotenoids were shaken into benzene, leaving the chlorophyll in the aqueous hypophase. The carotenoids were chromatographed from 10 per cent acetone in petroleum ether on a column of aluminium oxide. The neoxanthin fraction from *Euglena* was purified further by crystallizing the pigment from diethyl ether-petroleum ether. Further details of extraction and chromatography will be given elsewhere⁴.

Fig. 1A is the absorption spectrum of neoxanthin in ethanol. The major peaks of absorption are at 466 and 437 mμ, as compared with 467 and 437 mμ reported by Strain¹.

As shown by Fig. 1B, the addition of a trace of hydrochloric acid results in a hypsochromic displacement of about 18 mμ. This shift is characteristic of the isomerization of a single 5:6 epoxide (I) to the 5:8 furanoid oxide (II), with the removal of one double bond from conjugation⁵.

No separation of the pigments from the two sources could be achieved in a mixed chromatogram on a column of aluminium oxide (Merck) 'weakened' by the addition of 5 per cent water. The column was developed slowly with 40 per cent acetone in petroleum

Table 1. PARTITION COEFFICIENTS OF NEOXANTHIN

Source	Ratio of pigment in epiphase (petroleum ether) to pigment in hypophase (aqueous methanol):	
	60% methanol	50% methanol
<i>Euglena</i>	8:92	37:63
Barley	10:90	34:66

ether; 100 per cent acetone; 2 per cent and finally 4 per cent ethanol in acetone. With the addition of ethanol to the eluant, the carotenoid migrated slowly as a single band.

Quantitative partition coefficients, measured by the method of Petracek and Zechmeister⁶, are given in Table 1. There can be little doubt that the pigment isolated from *Euglena gracilis* and neoxanthin isolated from barley are identical, and that this pigment is a mono-epoxide carotenoid. The degree of purification we feel accounts for the minor differences in absorption spectra.

From its spectral similarity to violaxanthin (ref. 1 and unpublished work by us) and neurosporene⁷, this pigment appears to have only nine conjugated double bonds. Inasmuch as the epoxide group is in the 5:6 position, 5':6' must be saturated. Neoxanthin is much more hypophasic in partition tests than antheraxanthin (3,3'-di-hydroxy-5:6-epoxy-β-carotene)⁴. This and the firm adsorption during chromatography indicate the presence of a fourth polar group, such as a third hydroxyl.

Table 2. ELEMENTARY ANALYSIS OF NEOXANTHIN (DATA FROM STRAIN (1))

C H	Predicted for.		Observed (average and range of four analyses)
	C ₄₀ H ₅₅ O ₄	C ₄₀ H ₅₅ O ₄	
	79.38 9.41	79.70 9.69	79.37 9.87 (79.02-79.70) (9.50-9.78)

Strain, from his elementary analysis, suggested that the results fit the general formula C₄₀H₅₅O₄. We believe his results could be somewhat better represented by the formula C₄₀H₅₅O₄ (Table 2). On the basis of these results, the spectral characteristics, behaviour on partition, and adsorption we propose the following tentative structure (III) for neoxanthin:

Neoxanthin 3,3',5'(or 6')-tri-hydroxy-6'(or 5')-hydro-5:6-epoxy-β-carotene).

It should be pointed out that this structure is a possible intermediate in the formation of the di-epoxide, violaxanthin.

It also appears likely that foliixanthin, a mono-epoxide of unknown structure reported by Chlcnoký *et al.*⁸ as present in the leaves and fruit of the yellow paprika, is identical with neoxanthin.

This investigation was supported in part by a grant (B-2077) to one of us (T. H. G.) from the Institute of Neurological Diseases and Blindness, and a grant (A-2087) to the other (N. I. K.) from the Institute of

Arthritis and Metabolic Diseases, United States Public Health Service.

A Method for concentrating Solutes of High Molecular Weight

CONCENTRATION of diluted aqueous solutions of labile solutes of high molecular weight, such as proteins, is often difficult in the laboratory as well as on a technical scale. We wish to present a mild concentration method, which seems to be useful in such cases.

This method is founded on the special property of a cross-linked dextran 'Sephadex' (Pharmacia, Uppsala (Sweden), which, even after swelling to a gel in aqueous media, will not admit large molecules, while there is little or no restriction of the diffusion of smaller molecules. If, therefore, dry 'Sephadex' is added to a solution, a concentration of solutes of high molecular weight is obtained corresponding to the amount of water taken up by the swollen grains. At the same time, salts and other solutes of low molecular weight are removed to an extent that ionic strength and pH remain approximately constant during the procedure.

As an example of the applicability, we wish to report an experiment where the liquid medium from a culture of *Polyporus versicolor* was concentrated prior to the isolation of cellulase. The purification of this enzyme will be described in greater detail elsewhere (Pettersson, G., Cowling, E., and Porath, J.).

7.5 litres of clarified culture medium were divided into three equal portions and 750 gm. 'Sephadex G-25' were added to each of these. The sieve fraction of this material was 50-100 mesh and its water regain was 2.6 gm. per gm. of dry 'Sephadex'. The thick suspension was stirred for 10 min. to obtain complete swelling of the gel, after which the gel grains were separated from the concentrated enzyme solution in a basket centrifuge (M.S.E. 3000). The centrifugation was started with a moderate centrifugal field, which was progressively augmented as the flow decreased. The filter cake was then washed by spraying a small amount of water centrally. The centrifugates and washes were pooled and subjected to an additional concentration step. At this stage the volume of the solution was small enough to be handled in one operation. After a third treatment the volume was reduced to an extent which made further purification by traditional methods more convenient. The concentration in three steps was accomplished in less than 4 hr. in spite of the large

Table 1. CONCENTRATION OF CELLULASE WITH 'SEPHADEX G-25'

	Enzyme solution (ml.)		Test quantity (ml.)	Activity (units per ml.)	Total activity
	In	Out			
Original sample	7,500		1.0	0.532	4,000
First step					
Main fraction	7,500	3,045	1.0	1.245	3,790
First wash	300	300	1.0	0.400	120
Second wash	300	274	1.0	0.105	29
Second step					
Main fraction	2,930	1,130	0.5	3.816	4,310
First wash	117	122	0.5	2.196	268
Second wash	117	92	0.5	0.418	39
Third step					
Main fraction	1,020	410	0.1	8.48	3,480
First wash	41	34	0.1	2.58	88
Second wash	41	31	0.1	0.46	14
Third wash	41	26	0.1	0.19	5

number of operations. (It should be possible to reduce the time required to about 1 hr. by omitting the washings and by using a larger centrifuge in the first step.) The process was followed by determination of the cellulase activity as measured by the increase in the number of reducing end-groups¹. The results obtained are given in Table 1.

The determination of activity is somewhat uncertain, as can be seen in the value for the main fraction of the second step. It is evident that this value is too high when compared to the original activity. According to the results in Table 1, the cellulase is almost quantitatively recovered in the 15-fold concentrated solution. The low activities in the washes show that it is possible to separate the concentrate almost completely from the swollen gel-grains quite easily.

For the application of the method described here, the following requirements must be fulfilled by the water-absorbing substance: (1) it should swell rapidly in water; (2) it should be easily and quantitatively separable from the concentrate; (3) it should be insoluble and not contaminate the concentrate; (4) it should not adsorb solutes which are to be concentrated.

Generally all these demands seem to be satisfied by 'Sephadex', if an appropriate particle size is used. Its upper limit is determined by requirement (1), and requirement (2) determines the lower limit. According to our own experience, only a small amount should pass a 100-mesh sieve.

Several procedures have been tried to separate the swollen gel-grains from the concentrate. The method described here, using a basket centrifuge, is particularly suitable for concentrating large volumes, while filter adapters in centrifuge tubes have been used when the concentration is carried down to a 1-ml. volume. The separation can, of course, also be made by filtration with suction or pressure; but losses are in general higher. Experiments have also been made to separate the concentrate in a column. For this purpose the suspension of gel in the concentrate is poured into a column and the concentrate is displaced by water. The method gave satisfactory results when the packing was carried out in such a way as to give a sharp boundary between the concentrate and the displacer.

Concentration with 'Sephadex' has been used for other substances sensitive to evaporation or freeze-drying, such as choline esterase, pancreatic lipase, phosphatases, and phosphodiesterases. Concentration of pepsin has been described by one of us². In connexion with paper electrophoresis, this method has been used routinely.

Generally, very high recoveries have been obtained, amounting to more than 90 per cent at 10–20-fold concentration. In connexion with experiments involving some proteins of low molecular weight (cytochrome *c* and a phosphatase from *E. coli*), some complications have appeared. A considerable part of the activity remained in the gel and could be recovered only after extensive washing of the filter cake. Difficulties will probably arise also in the concentration of very viscous solutions.

It is of practical importance that the 'Sephadex' could be regenerated. This was done by first washing with water, followed by two suspensions of the material in ethanol, and drying at 80° C. The dried substance could then be used for new concentration experiments without any detectable difference in its properties.

Biogenesis of Lysergic Acid in Ergot

SEVERAL schemes have been proposed for the biogenesis of the medicinally valuable lysergic acid moiety of the ergot alkaloids^{1–5}. Recently, it was shown by Taber and Vining⁶, and later verified by Baxter *et al.*⁷, that tryptophan (β -¹⁴C) serves as a precursor for lysergic acid. Groger and co-workers⁸ demonstrated that tryptophan (β -¹⁴C) is also a precursor for the chemically related clavine alkaloids, which are produced by certain strains of ergot; but the carboxyl group of tryptophan does not enter the molecule. The nature of the precursor of the remaining portions of lysergic acid and of the clavine alkaloids has remained a puzzle. Groger⁸ demonstrated that, when acetate (1-¹⁴C) was fed to saprophytic cultures of ergot, the radioactivity was incorporated into the clavine alkaloids. Since the alkaloids were not degraded, the biogenetic significance of this work is not clear.

Mevalonic acid has been recognized as a key compound in the biogenesis of isoprenoids, terpenoids, and steroids. In 1959, Groger⁸ added mevalonic acid to the saprophytic culture medium, but found no significant increases in total production of clavine alkaloids. We have found that mevalonic acid serves as the precursor for the isopentenyl portion of lysergic acid:

So far as we are aware, this is the first demonstration of mevalonic acid serving as a biogenetic precursor for an alkaloid. (Since this communication was written, clavine alkaloids have been derived from

mevalonic acid by Birch, A. J., *et al.*, *Z. Naturforsch.*, **15**, b, 141; 1960.)

A series of cultures of *Claviceps purpurea* (PRL 1578) were grown in batches of 40 ml. of liquid nutrient medium in 125-ml. flasks. After 15–30 days, 1 μ o. of radiologically pure mevalonic acid-2-¹⁴C (21.9 mgm. = 1 mc.) was added to each flask. Two weeks later the medium and the mycelium were separated by filtration, the medium made alkaline with ammonia, and the alkaloids extracted with chloroform. The mycelium was dried, finely powdered, and defatted with petroleum ether. The alkaloids were extracted with ammoniacal ether. The two alkaloidal extracts were evaporated to dryness, and the residues were dissolved in a mixture of chloroform and isopropanol (3:1); a portion was spotted on formamide-impregnated paper⁹ and chromatographed (descending) with carbon tetrachloride/chloroform/benzene (7:2:1). In this solvent system the ergot alkaloids are separated well and in order of increasing *R_F* values: ergotamine, ergosine, ergotaminine, ergosmine, ergocornine plus ergocristine, ergo-cryptine, ergocorninine plus ergocristinine, and ergocryptinine; the water-soluble ergometrine and ergometrinine remain at the origin.

Ergotamine and ergosine were eluted separately from the carbon tetrachloride–chloroform–benzene–chromatogram with 50 per cent ethanol and hydrolysed according to the method of Jacobs and Craig¹⁰. The hydrolysate was chromatographed with butanol/acetic acid/water (4:1:1) on Whatman No. 1 paper. Autoradiograms showed the radioactivity to coincide exactly with the location of lysergic acid (*R_F* 0.40) as established from its fluorescence under ultra-violet light and the blue colour given by this indolic compound with Ehrlich's reagent. The behaviour of the compound was identical to that of authentic lysergic acid and to the behaviour of lysergic acid in the hydrolysate of pure ergotamine.

For the separation, identification, and isolation of ergometrine a second portion of the alkaloid mixture was chromatographed (descending) in butanol–acetic acid–water on Whatman No. 1 paper. In this solvent system ergometrine has an *R_F* of 0.60 while the peptide-type alkaloids have an *R_F* of 0.85. Both these fluorescent radioactive areas were eluted separately with 50 per cent ethanol, the eluate hydrolysed and chromatographed (descending) with butanol–acetic acid–water on Whatman No. 1 paper. In both cases the lysergic acid was found to be radioactive as revealed by autoradiograms. All the radioactivity of the alkaloids resided in the lysergic acid.

Mevalonic acid did not enter appreciably the general metabolism of the mould. More than 90 per cent of the radioactivity of converted mevalonic acid-2-¹⁴C was found incorporated into the lysergic acid portion of the ergot alkaloids. The petroleum ether fraction of the mycelium contained less than 10 per cent of the total added radioactivity. The amino-acids which were extracted from the mycelium showed no radioactivity.

A more detailed and extended account of this work will be published elsewhere.

This investigation was supported by grants from Purdue Research Foundation XR fellowship No. 2255, and the National Institute of Health Contract No. RG-6606. PHYSIOLOGY

Rectifying Properties of Heart Muscle

A FACTOR of likely importance in the genesis of the long-lasting action potentials of vertebrate heart muscle is the influence of membrane potential on the potassium permeability of the fibres. That a difference here exists between cardiac muscle and nerve is evident from Weidmann's¹ demonstration of a low slope conductance during the plateau of the action potential. But little information is so far available on the voltage dependence of the membrane conductance under conditions designed to avoid the generation of action potentials.

To study this point, so far as the technical limitations imposed by the structure of cardiac muscle at present allow, excised Purkinje fibres from sheep ventricles were used. While sharing the essential electrical properties of myocardial tissue, these fibres do not produce a mechanical response on depolarization; they are also insensitive to parasympathomimetic substances so that choline chloride or sucrose may be used as a substitute for extracellular sodium chloride to abolish excitability.

Fig. 1, A and B, shows how the membrane conductance of a Purkinje fibre in sodium-deficient

solution depends on the direction and magnitude of the polarizing current. An outward current of 0.31 μ amp., for example, produced the same voltage deflexion as is caused by nearly twice as great an inward current. Allowing for the cable properties of the fibre, this means that the conductance to a depolarizing current may be about four times less than to a hyperpolarizing current. Since the contribution of chloride ions to the membrane conductance of cardiac muscle is small², a decrease in the potassium conductance presumably occurs on depolarization. The direction of the potassium conductance change in Purkinje fibres is thus opposite to the predominant change in nerve³, but has a parallel in skeletal muscle⁴.

With strong depolarizing currents a decline in the electrotonic potentials during the pulse may be observed, suggesting a gradual increase in conductance. This second effect probably accounts for the S-shaped relation between the amplitude of the electrotonic potential at the end of a long pulse and the polarizing current (Fig. 1 B), but over the physiological range the conductance remains below its value at the resting potential.

The slope conductance decreases appreciably over the range occupied by the slow diastolic depolarization in spontaneously beating preparations¹. This alnearity may require consideration in interpreting the resistance changes observed during the pacemaker potential⁵.

Cardiac Action and Pacemaker Potentials based on the Hodgkin-Huxley Equations

SINCE the equations describing the nerve action potential were formulated by Hodgkin and Huxley¹, the range of phenomena to which they have been shown to apply has been greatly extended. Huxley² has applied them to the influence of temperature on the propagated response and to the repetitive firing observed in low calcium concentrations. More recently, Fitzhugh³ has shown that the long action potentials induced by tetraethylammonium ions in squid nerve may also be reproduced.

The computations described in this communication were carried out with the aim of reconstructing the long-lasting action potential and pacemaker potential of cardiac muscle. Although this work was done independently, the results agree with those of Fitzhugh in showing that action potentials of long duration may be accounted for by Hodgkin and Huxley's formulation of the membrane properties. The description of the potassium current, however, differs from that used by Fitzhugh and provides a better description of the conductance changes.

The equations I have used to describe the sodium current are very similar to Hodgkin and Huxley's,

Fig. 1 A. Superimposed tracings of electrotonic potentials from a sheep's heart Purkinje fibre. Sodium ions in Ringer's solution replaced by choline. Depolarization is shown in an upward deflection from a resting potential of -92 mV. Two closely spaced KCl-filled intracellular electrodes were used to record the membrane potential and to pass practically rectangular current pulses of a strength indicated by the figures on each record. B. Current-voltage relation for the same preparation. Ordinate, membrane potential at end of current pulse lasting 700 msec. Abscissa, total membrane current

those for h (the variable describing the availability of sodium carriers) being based on Weidmann's⁴ experiments on the availability of sodium carriers in Purkinje fibres.

The behaviour of the potassium battery in cardiac muscle differs from that in nerve in that the potassium conductance (G_K) falls when the membrane is depolarized.⁵ A small delayed increase in conductance appears to be present when large currents are used, but this is not great enough for the conductance of the depolarized membrane to exceed the resting conductance. For the purpose of setting up equations to describe this behaviour, it is convenient to suppose that potassium ions move through two types of channel in the membrane. In one, G_K is an instantaneous function of the membrane potential and falls when the membrane is depolarized. A simple empirical equation has been used to describe the current in this channel. In the other type of channel the rectification is in the opposite direction and occurs with a delay. The conductance of this channel may be described by Hodgkin and Huxley's equations for delayed rectification with two modifications. First, the magnitude of this conductance must be small; accordingly the maximum conductance ($\bar{G}_K$) has been made less than 1/50 of that in nerve. Secondly, the time constants have been made very much longer to take account of the slow onset of the effect.

The membrane capacity was taken as 12 $\mu\text{F./cm.}^2$ (ref. 4), and the absolute values of the various conductances were adjusted to give a resting membrane resistance of about 2,000 ohms/cm.² (ref. 4).

Fig. 1. A, Computed action potential. The integration was started by displacing the membrane potential to -60 mV., which is equivalent to a very short cathodal pulse of 3.6×10^{-7} coulombs/cm.². B, Time course of computed conductance changes on a logarithmic scale. G_K , potassium conductance, G_{Na} , sodium conductance. The potassium and sodium equilibrium potentials were set at -100 mV. and $+40$ mV. respectively.

Fig. 2. Solution to equations in which the membrane potential is unstable in diastole so that pacemaker activity occurs. In this case, the potential at which the steady state sodium and potassium currents are equal and opposite is -38 mV. and an unstable state at this potential corresponds to a second solution to the equations.

The equations were set up on a digital computer and were integrated by a numerical approximation using a step length of 0.05 m.sec. during the initial spike of the action potential and 0.3 m.sec. during the slower phases. In this connexion I should like to thank Dr. R. A. Buckingham, director of the University of London Computer Unit, for permission to use *Mercury* for this purpose, and Dr. M. J. M. Bernal and other members of the Computer Unit staff for advice on programming.

It was found that computed responses resembling action potentials of different durations could be obtained by inserting appropriate values for the constants in the equations for m (the variable describing the activation of sodium carriers). One of the solutions is shown in Fig. 1. It can be seen that the general shape of the action potential (A) corresponds very closely to that observed experimentally in Purkinje fibres⁴. The time-course of the computed conductance changes is shown in Fig. 1B. After an initial 'spike', the sodium conductance (G_{Na}) settles down to a value during the plateau which is about 8 times its resting value. G_K by contrast is below its resting value throughout the duration of the plateau.

The total membrane conductance ($G_K + G_{Na}$) rises during the plateau, but the slope conductance (determined by adding current to the equations at different times during the integration) was found to decrease. This is the result of a decrease in the sodium slope conductance which becomes negative towards the end of the plateau. Although the slope conductance during the plateau falls to a value which is equal to the resting conductance, the decrease was not so great as that observed experimentally⁴. This may be the result of a defect in my equations which over-estimate the potassium current produced by large depolarizations of the membrane.

If a large enough repolarizing current is added to the equations during the plateau, an all-or-nothing repolarization is initiated. The threshold for this phenomenon is about -30 mV. at the middle of the plateau, which is in fair agreement with that found experimentally by Weidmann⁴.

In these equations there is always at least one potential at which the steady state sodium and potassium currents are equal and opposite. In the computations just described, this forms the resting potential and the system is stable unless excited. A

small change in the constants in the equations for m is sufficient to make the system unstable in diastole, and pacemaker activity then occurs. Such a solution is shown in Fig. 2. However, in order to bring about repolarization in this case a larger delayed potassium conductance had to be assumed. It is not yet known whether this is a necessary feature of the equations and further computations are being made to test this point. Nevertheless, the sensitivity of the computed pacemaker potential to changes in ionic conductance has been shown to correspond quite well with the experimental information available⁴.

Relative Vascularity of Certain Anatomical Areas of the Brain and Other Organs of the Rat

It need scarcely be pointed out that for the meaningful interpretation of the results of work where an exogenous material is administered to an animal and the assay performed on dissected areas of tissues with their content of blood, as is usually the case, it is frequently necessary to know the contribution of blood to the respective areas. This is particularly true if the concentration of a given substance is much greater in the blood than in the tissues.

Several approaches were made by different investigators¹⁻⁵ to determine the vascularity of the central nervous system of the cat, but so far as we know, nothing similar has been reported for the rat since the earlier work of Craigie⁶. He used the method of direct capillary counts of specimens from animals injected with carmin gelatin to determine the relative vascularity, but the limitations of this method are obvious. Furthermore, it has not included all the anatomical areas of interest to us. In 1955 Oeff and König⁷ reported the blood content of several organs of the rat including whole brain in the non-bled out, bled out, and perfused animals using erythrocytes labelled with phosphorus-32. They did not, however, determine the blood content of the various anatomical areas of brain. In their work on the cat, Barlow *et al.*¹ have approached this problem using human serum albumin labelled with iodine-131 and demonstrated the relative vascularity by means of densitometric measurements of the autoradiograms.

Their technique consisted of killing the animal by intracardiac injection of a saturated solution of potassium chloride, dissecting out the brain, hardening it on a bed of dry ice followed by sectioning. The whole operation was performed at room temperature (29°). They observed that "tissue radioassay data of an anatomical structure within a single animal and of the same structure from animal to animal showed wide variation and were, therefore, useless for quantitative purposes. It is clear that dissection-sampling technique inadvertently included varying amounts of large blood vessels containing highly concentrated radioactivity giving rise to gross inconsistencies". However, by selecting areas on the autoradiogram

corresponding to tissue areas containing blood within only small blood vessels and capillaries and avoiding large blood vessels, they were able to obtain values in good agreement with those found by others using capillary counting techniques. The problem referred to by Barlow *et al.* is a general one and arises also in distribution and metabolism work where such techniques are utilized.

It seems that the major factors which contribute to the inconsistencies in similar experiments are: (1) Varying amounts of residual blood that is retained in the brain tissue as a result of the varying loss which is inevitable in the process of dissection. (2) Contamination from blood which is also unavoidable. It is not difficult to see that in this case, where there is a tremendous concentration gradient from blood to the adjoining tissue, how adversely this situation can affect the results. (3) Since the operation is performed at room temperature, there is some condensation of moisture on the cold surface of brain slices which may lead to spreading, leaching, and further contamination of areas. The influence of these factors is greater when one is dealing with the very small areas of brain. In the present work, we have avoided these difficulties by using the following technique.

White male rats, weighing 250-300 gm., were injected by the tail vein with 10 μ c./100 gm. of human serum albumin labelled with iodine-131 (RISA, Abbott). Pentobarbital sodium (4 mgm./100 gm.) was also administered along with the albumin to facilitate withdrawal of blood by intracardiac puncture, minimizing at the same time influences of stress on the animal. At the end of 15 min., 1 ml. of blood was withdrawn from the heart, and the animal was killed by rapid immersion in acetone-carbon dioxide mixture (-78°). It was then transferred to a refrigerated room (-10°), allowed to remain for 1 hr., and all subsequent operations were carried out there. The brain was chiselled out of the frozen animal with a 6 mm. wide chisel and after removal of the meninges and the larger blood vessels on the surface, 2-3 mm. thick serial coronal sections were obtained by free-hand sectioning with a razor blade. The areas dissected from the central nervous system were: cerebral cortex, cerebral white matter, caudate nucleus, thalamus, hypothalamus, hippocampus, inferior colliculi, cerebellar cortex, medulla and spinal cord. Similarly, sciatic nerve, kidney cortex, kidney medulla, periphery of the left lateral lobe of liver, skeletal muscle, and adrenals were also dissected. Of these, the cerebral white matter and the cerebellar cortex were the most difficult to dissect with any degree of assurance. It is to be noted that during the whole operation, in view of the fact that it is performed in the refrigerated room on the frozen animal, there was neither loss of blood nor contamination by blood; nor was there any spreading of activity from the blood as a result of condensing moisture. The areas dissected were homogenized in 1.5 ml. of water, 1 ml. of the homogenate transferred to weighed glass tubes and the radioactivity determined in a well-type scintillation counter. The tubes containing homogenate were then dried to constant weight in a desiccator. Table 1 shows the results from 15 animals. The results are expressed as a ratio of the specific activity of the area over the activity of a microlitre of haemolysed blood of the same animal taken at the time of killing, times 10³. An absolute determination of the vascularity was not attempted in this investigation, but it merely sought to establish a set

Table 1. RELATIVE BLOOD CONTENT OF DIFFERENT AREAS OF THE BRAIN AND CERTAIN OTHER ORGANS OF THE RAT

Area	counts/min./mgm dry wt * $\times 10^3$ counts/min./ μ l. blood
Cerebral cortex	8.49 $\pm$ 0.69
Cerebral white	8.33 $\pm$ 0.33

of ratios which is adequate for the intended use of this information.

The experimental conditions for this work were carefully chosen so that identical conditions could be adapted for studies concerning drug distribution and permeability changes within the central nervous system. We are at present investigating two classes of compounds: one that enters the brain tissue rapidly and one that does not cross the blood-brain barrier, and it is hoped that the results will show the usefulness of the technique and the validity of the results obtained with iodinated albumin. It may be concluded from the present experiments that: (1) the vascularity of the central nervous system of the rat is certainly not uniform and the interpretations arrived at in the past on the basis of the average value of 0.024 ml. of blood per gm. of brain tissue⁸ may need reconsideration. (2) There is a variation (for the range see Table 1) from animal to animal in the blood content of various areas. This would suggest the need for study of a large number of animals, particularly in the case of a substance the blood concentration of which is not much different to the concentration in tissue. (3) The results presented in Table 1 provide a reference scale which is of use in the study of distribution of drugs within the central nervous system of rat when the contribution of vascularity is also to be taken into account.

This investigation was supported in part by a research contract No AT(11-1) 847 from the Atomic Energy Commission.

Isolation of Glomerula from Rat Kidney

In contrast to the renal tubular system the glomerulum has not received as much attention biochemically as it deserves. This is mostly due to the difficulties in isolating a pure glomerular fraction. Only during the past ten years have a few methods been worked out which are, however, too complicated and time-consuming for the study of enzyme patterns in single normal or diseased animals. McCann's method¹, using manually isolated glomerula from frozen-dried sections, is limited by the small amount of tissue available for analysis. To obtain larger samples, attempts have been made to isolate the glomerula from crude kidney homogenate. Liberation of the glomerula from surrounding tissue was achieved by using a Potter-Elvehjem tissue homogenizer² with a mismatched plunger³ or pushing the kidney through a fine-meshed wire gauze⁴⁻⁶. The purification of the glomerular fraction was performed either by repeated centrifugation⁴, by filtration through a layer of glass balls⁷, or by magnetic attraction following intra-arterial injection of iron trapped in the glomerula⁸. No detailed information on purity or yield of the glomerula was given. For enzyme work on normal and diseased glomerula a method had to be developed allowing rapid, and technically simple, isolation.

Table 1. DISTRIBUTION OF ALKALINE PHOSPHATASE IN FRACTIONS H, M, T AND G

Fraction	N	μ M p-Nitrophenol/mln./mgm. protein $\bar{x}$	s
H ('homogenate')	8	0.651	0.220
M (medulla)	7	0.030	0.015
T ('tubular material')	7	0.662	0.293
G (glomerula)	5	0.180	0.080

This was achieved by pushing out the glomerula of the surrounding tubules in a homogenizer with an ill-fitting pestle³, centrifuging the resulting crude homogenate against an osmotic gradient and eliminating impurities by sieving several times through graded nylon mesh sieves. The capsule of kidneys of rats weighing 180-200 gm. is stripped off, the hilar structures and the medulla (Table 1: fraction M, 20 per cent w/v, homogenate in isotonic sucrose) dissected away. The remaining cortex is cut into small pieces with scissors, suspended in isotonic sucrose (final concentration 20 per cent, w/v) and coarsely ground in a Potter-Elvehjem apparatus² using an unmatched plunger until the tissue pieces have disappeared (fraction H). The suspension is then put through a nylon HD 250- μ mesh sieve (obtained from Zürcher Beuteltuchfabrik A.G., Am Schanzengraben 15, Postfach 1123, Zurich 22). In the meantime, a plastic cylinder (Fig. 1,b) with a 100- μ mesh sieve as the bottom (e) was inserted into a centrifuge tube (a) filled with 25 per cent sucrose solution up to 2 cm. above the level of the sieve (d). 5-10 ml. of fraction H are layered on the hypertonic sucrose in the plastic tube (c), and centrifuged for 10 min. at 3,000 r.p.m. in a refrigerated centrifuge. There then appears at the top a yellowish viscous fluid containing microscopical particles which are believed to be of tubular origin because of their high content in alkaline phosphatase (fraction T). On the net are found small pieces of tubules and the majority of the glomerula. This material is resus-

Fig. 1. Centrifuge tube (a) with plastic insert (b) for centrifugation through a mesh sieve (c) against an osmotic gradient (d)

pendent in 8 per cent sucrose and filtered through a 150- μ sieve which eliminates most of the tubular fragments. The remaining impurities are removed by two or three more filtrations through 100–200- μ mesh sieves. A photomicrograph of the final glomerular fraction *G* is presented in Fig. 2 (courtesy of Prof. E. Hintzsche, director of the Anatomical Institute, University of Berne). Most of the glomerula are devoid of their capsule and only occasional specimens still show an intact Bowman capsule (right lower corner). It is important to carry out all the manipulations in the cold and to control the procedure by microscopic examination. Even so, the whole process can be completed within 1 hr. of killing the animals.

To determine the yield of glomerula, counts were made from fractions *H* and *G*. Assuming 27,000 glomerula per gm. rat kidney², 29 ± 8 per cent ($\bar{X} \pm s$; $N = 7$) of glomerula are recovered in fraction *H* and 7 ± 3 per cent in fraction *G*. This suffices for the assay of a number of enzymes and for manometric studies of the glomerula isolated

Fig. 2. Photomicrograph of fraction *G*

from one animal. To obtain a quantitative measure of the purity of the glomerular fraction, alkaline phosphatase activity was determined¹⁰ in homogenates and based on protein content¹¹. The results (Table 1) reveal a three-fold concentration of this enzyme in fractions *H* and *T* as compared to fraction *G*. Work on a number of other enzymes, oxygen uptake and glycolysis of isolated glomerula will be presented elsewhere.

Active Transport of Sodium by Isolated Frog Skin in Relation to Metabolism of Acetate labelled with Carbon-14

ALTHOUGH it is well established that isolated frog skin uses energy for the active transport of sodium, little is known about the metabolic processes providing this energy. Huf¹ showed that monobromacetate caused a decrease in potential across the frog skin which could be reversed by pyruvic and lactic acids, but not by glucose. Similar results were obtained by Francis and Gatty².

These experiments suggest, but do not clearly establish, that exogenous metabolites can be used by the skin. The use of appropriate metabolites labelled with carbon-14 appeared to offer an approach to this problem. Preliminary work by one of us (K. Z.) done in the Department of Biophysics, Purdue University, indicated that the isolated frog skin could take up and metabolize a number of carbon-14-labelled compounds.

The short-circuiting technique of Ussing and Zerahn³ was employed for determining sodium transport. The apparatus used was only slightly modified from that of Zerahn⁴. The skin was placed as a barrier between two glass compartments so that each could be individually filled with solution, stirred, drained and refilled with ease. The compartment facing the inner side of the skin was filled with Ringer solution to which was added the labelled metabolite to be studied, and vasopressin to obtain a higher rate of sodium transport. Streptomycin was also added to this solution in about half the experiments to reduce bacterial growth.

In other experiments, it was found that isotopic equilibrium is not attained in several hours of equilibration. A preliminary 2-hr. period of contact of the skin with labelled metabolite was therefore allowed, and the bathing solutions of this period were discarded. The medium from subsequent experimental periods was acidified and the released carbon

dioxide collected in a small volume of sodium hydroxide using a spiral absorption apparatus developed by Holm-Jensen (Holm-Jensen, J., unpublished work).

The radioactivity of carbon dioxide samples was compared to the radioactivity of the inside solution and thus permitted calculation of the amount of tracer metabolite utilized.

The labelled metabolites were obtained from Amersham and were generally used at a level of 0.5 μ C. per period. Acetate was chosen as a representative metabolite and was used at a level of 1 mM.

During the transport period the compartment on the outside of the skin was filled with Ringer solution. In this way the sodium transport can be determined from the reading of the short-circuit current. Total production of labelled carbon dioxide and thus total labelled acetate utilization were determined.

To determine the amount of the radioacetate used which did not contribute to sodium transport, a blank period of non-transport was done during which the outside Ringer solution was replaced with distilled water. Other means of obtaining non-transport periods, such as the use of an applied potential of 150 mV. (inside positive), gave similar results.

Alternate 90-min. periods of non-transport and transport were carried out, and the average value of acetate carbon-14 used for two non-transport periods was subtracted from the value of the intervening transport period. The labelled metabolites contained some labelled carbon dioxide. No correction was made for this activity because it represented a minor fraction of the labelled carbon dioxide collected, and furthermore, calculation of the difference as above allows for the presence of a blank.

The following assumptions are made in the calculations: (1) Both the carbons of radioacetate contribute to production of carbon dioxide to about the same extent. This was confirmed in work with acetate-1-¹⁴C and acetate-2-¹⁴C. (2) For each mole of acetate metabolized, two molecules of oxygen are utilized. Since Zerahn⁴ and Leaf and Renshaw⁵ have shown that one molecule of oxygen is used for each 18 atoms of sodium transported, each mole of acetate used for transport will provide for the transport of 36 atoms of sodium. Each atom of sodium will thus require the use of 1/36 mole or 0.0278 mole of acetate. (3) From the net acetate used and the amount of sodium transported, the fraction of the sodium transport due to the use of the acetate of the medium is calculated.

The experimental findings are summarized in Table 1. It is clear that the added acetate can be utilized

by the isolated frog skin as is indicated by the first two columns and that it is utilized for sodium transport is shown by the third column. The fraction of the sodium transport supported by the metabolism of the exogenous acetate is given in the last column. (This is, furthermore, the relative specific activity in per cent of the radioacetate added.)

In similar work we have shown that lactate is used at a rate similar to acetate, but that glucose was metabolized to a smaller extent.

It can be concluded that: (1) The serosal surface of the isolated frog skin is permeable to exogenous acetate and lactate; (2) the skin can use these compounds for metabolism; (3) added metabolites can support sodium transport; (4) when the exogenous acetate is present at a level of 1 mM, an appreciable fraction of the total sodium transport can be directly related to the use of the added acetate.

An Adaptive Change in an Inbred Mouse Strain maintained in a Cold Environment

A STRAIN of A2G mice (*Mus musculus* L.), maintained for a number of generations in a room kept at -3° C., has progressively improved in ability to cope with the cold. The mice were obtained from Glaxo Laboratories, and had a long history of sib mating. When the breeding was begun in the cold environment, a parallel colony was started at 21° C. (controls). Members of a single litter were used to start the two colonies: one pair was kept at 21° C. and the other transferred to -3° C. These initial pairs were the parents of the first generation of mice studied. All subsequent breeding pairs too were litter mates, and were selected at random at the age of 5 weeks. Reproductive performance was recorded to the age of 28 weeks. There were few barren pairs in the cold, and only one after the fourth generation. One control pair, in the fourth generation, failed to produce young. The methods used, and some of the physiological changes in the mice kept in the cold, have already been described^{1-3,5}.

The evidence of a secular change in the response to cold comes from the loss of young between birth and 21 days (weaning). Fig. 1 shows that the controls had a consistent infant mortality of about 22 per cent. The mice in the cold lost nearly 80 per cent of the young in the second generation, but by the ninth generation they were losing 10 per cent or fewer.

The loss of young born to first-generation pairs in the cold was significantly lower ($P < 0.05$) than to those of the second generation. Since the parents of the mice of the first generation had been reared at 21° C., it seems likely that these mice provided a better uterine environment and milk supply than the second-generation parents. Other data, not yet published, tend to confirm this.

The secular improvement could be due to changes either in maternal performance or in the young; both could be involved. There was no evidence of a pro-
